# Thermal Neutron Capture of $^{64,66}\text{Cu}$

**Andrew M. Rogers**  
Nuclear Science Division  
Lawrence Berkeley National Laboratory

**USNDP / CSEWG**  
**11-06-2012**

- Introduction

- Motivation and method
- DICEBOX

- Experimental setup  
(Budapest research reactor)

- Preliminary analysis  $^{65}\text{Cu}(n,\gamma)^{66}\text{Cu}$

- Summary and outlook

$^{63}\text{Zn}$ 38.47 M $\epsilon$ : 100.00%	$^{64}\text{Zn}$ $\geq 7.0 \times 10^{20}$ Y 49.17% $2\epsilon$	$^{65}\text{Zn}$ 243.93 D $\epsilon$ : 100.00%	$^{66}\text{Zn}$ STABLE 27.73%	$^{67}\text{Zn}$ STABLE 4.04%
$^{62}\text{Cu}$ 9.673 M $\epsilon$ : 100.00%	$^{63}\text{Cu}$ STABLE 69.15%	$^{64}\text{Cu}$ 12.701 H $\epsilon$ : 61.50% $\beta^-$ : 38.50%	$^{65}\text{Cu}$ STABLE 30.85%	$^{66}\text{Cu}$ 5.120 M $\beta^-$ : 100.00%
$^{61}\text{Ni}$ STABLE 1.1399%	$^{62}\text{Ni}$ STABLE 3.6346%	$^{63}\text{Ni}$ 101.2 Y $\beta^-$ : 100.00%	$^{64}\text{Ni}$ STABLE 0.9255%	$^{65}\text{Ni}$ 2.5175 H $\beta^-$ : 100.00%

**PRELIMINARY**

- General improvements in the total radiative neutron-capture cross sections ( $\sigma_0$ ).
- Constrain spins, search for new transitions, and etc..
- Method:
  - Experimental data of thermal ( $n,\gamma$ ) cross sections on *elemental* Copper samples.
  - Generate simulated neutron capture decay schemes using the statistical decay code DICEBOX.
  - Compare measured *depopulation* from experiment to the *population* of levels generated by DICEBOX.

$$\sigma_0 = \sum \sigma_{\gamma}^{\text{exp}} (\text{g.s.}) + \sum \sigma_{\gamma}^{\text{sim}} (\text{g.s.})$$

- Simulates spectra of nuclear  $\gamma$  cascades using Monte Carlo methods.
- Below a *critical energy*,  $E_{\text{crit}}$ , the spectrum is considered to be complete.
- Above  $E_{\text{crit}}$ ,
  - Sets of levels are generated from a known level-density formula  $\rho(E, J^\pi)$
  - Samples and incorporates uncertainties due to Porter-Thomas fluctuations.

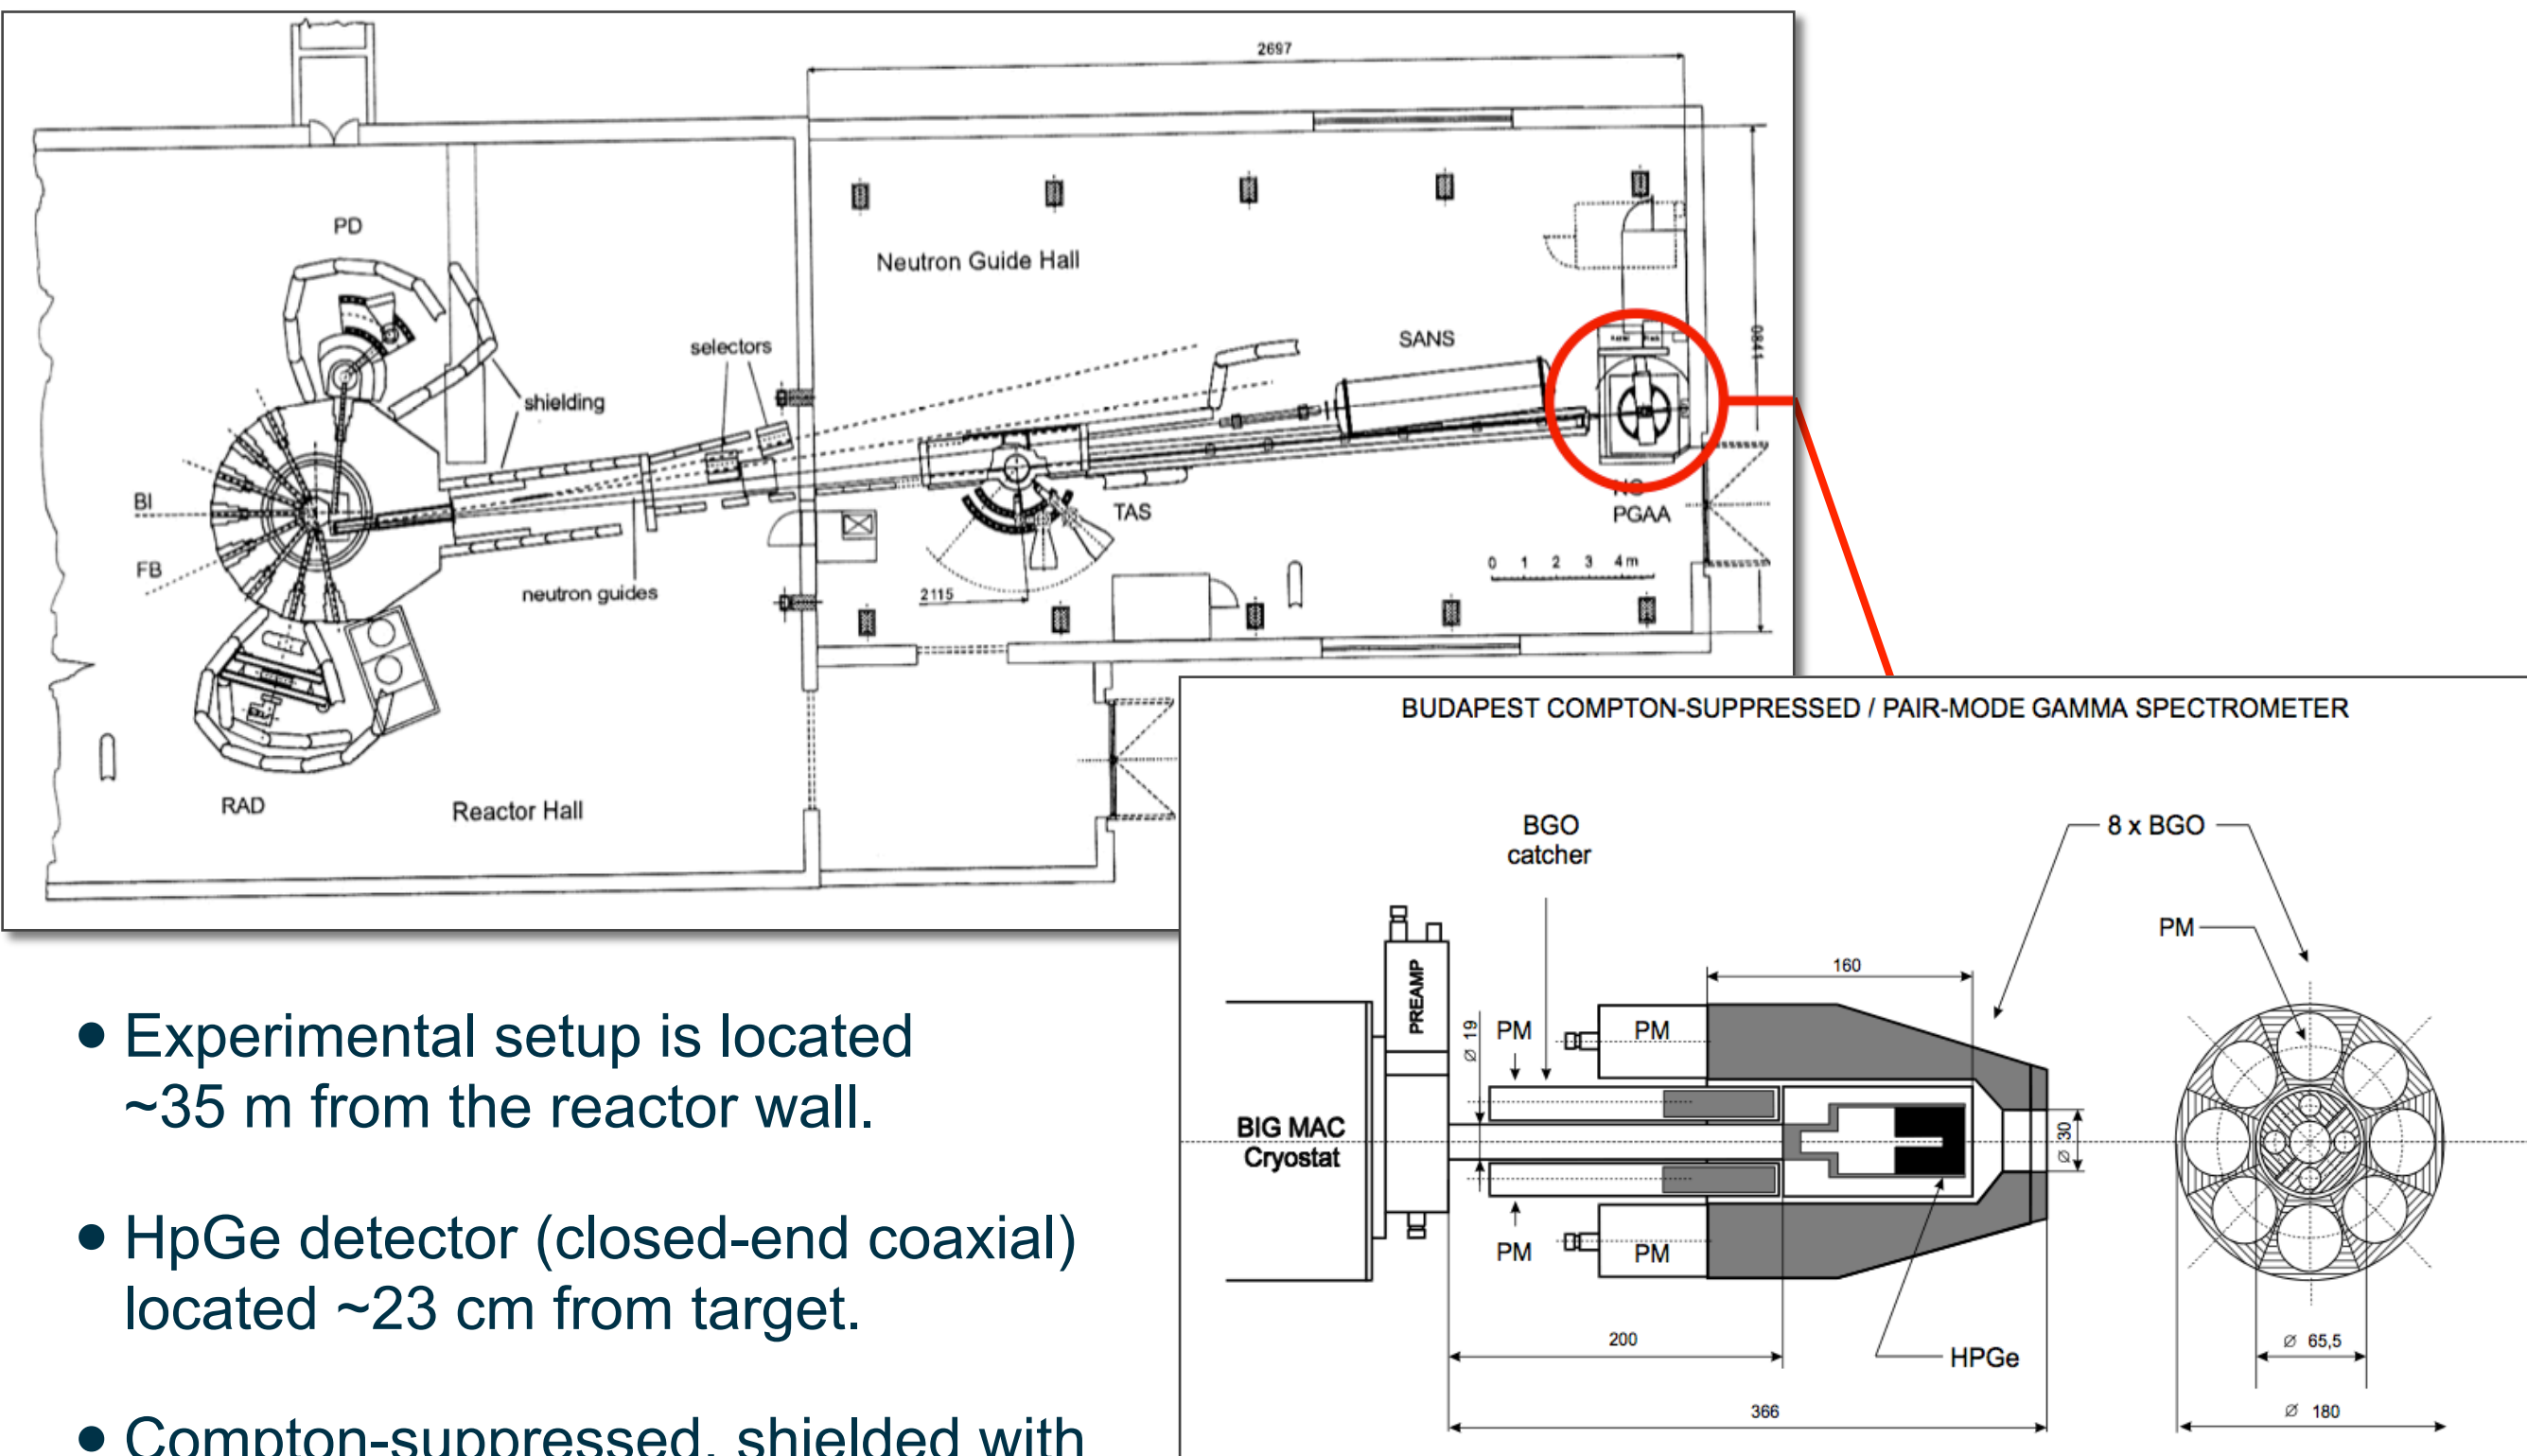

# Experimental setup - research reactor

- 10-MW Budapest research reactor
- Guided thermal-neutron beam
- Thermal flux:  $\sim 10^6 \text{ cm}^{-2}\text{s}^{-1}$
- Cold flux:  $\sim 10^7 \text{ cm}^{-2}\text{s}^{-1}$
- PGAA (Prompt Gamma Activation Analysis)
- Primary and secondary capture  $\gamma$  rays measured in low-background environment.
- No epithermal, fast, or high-energy neutrons!!!

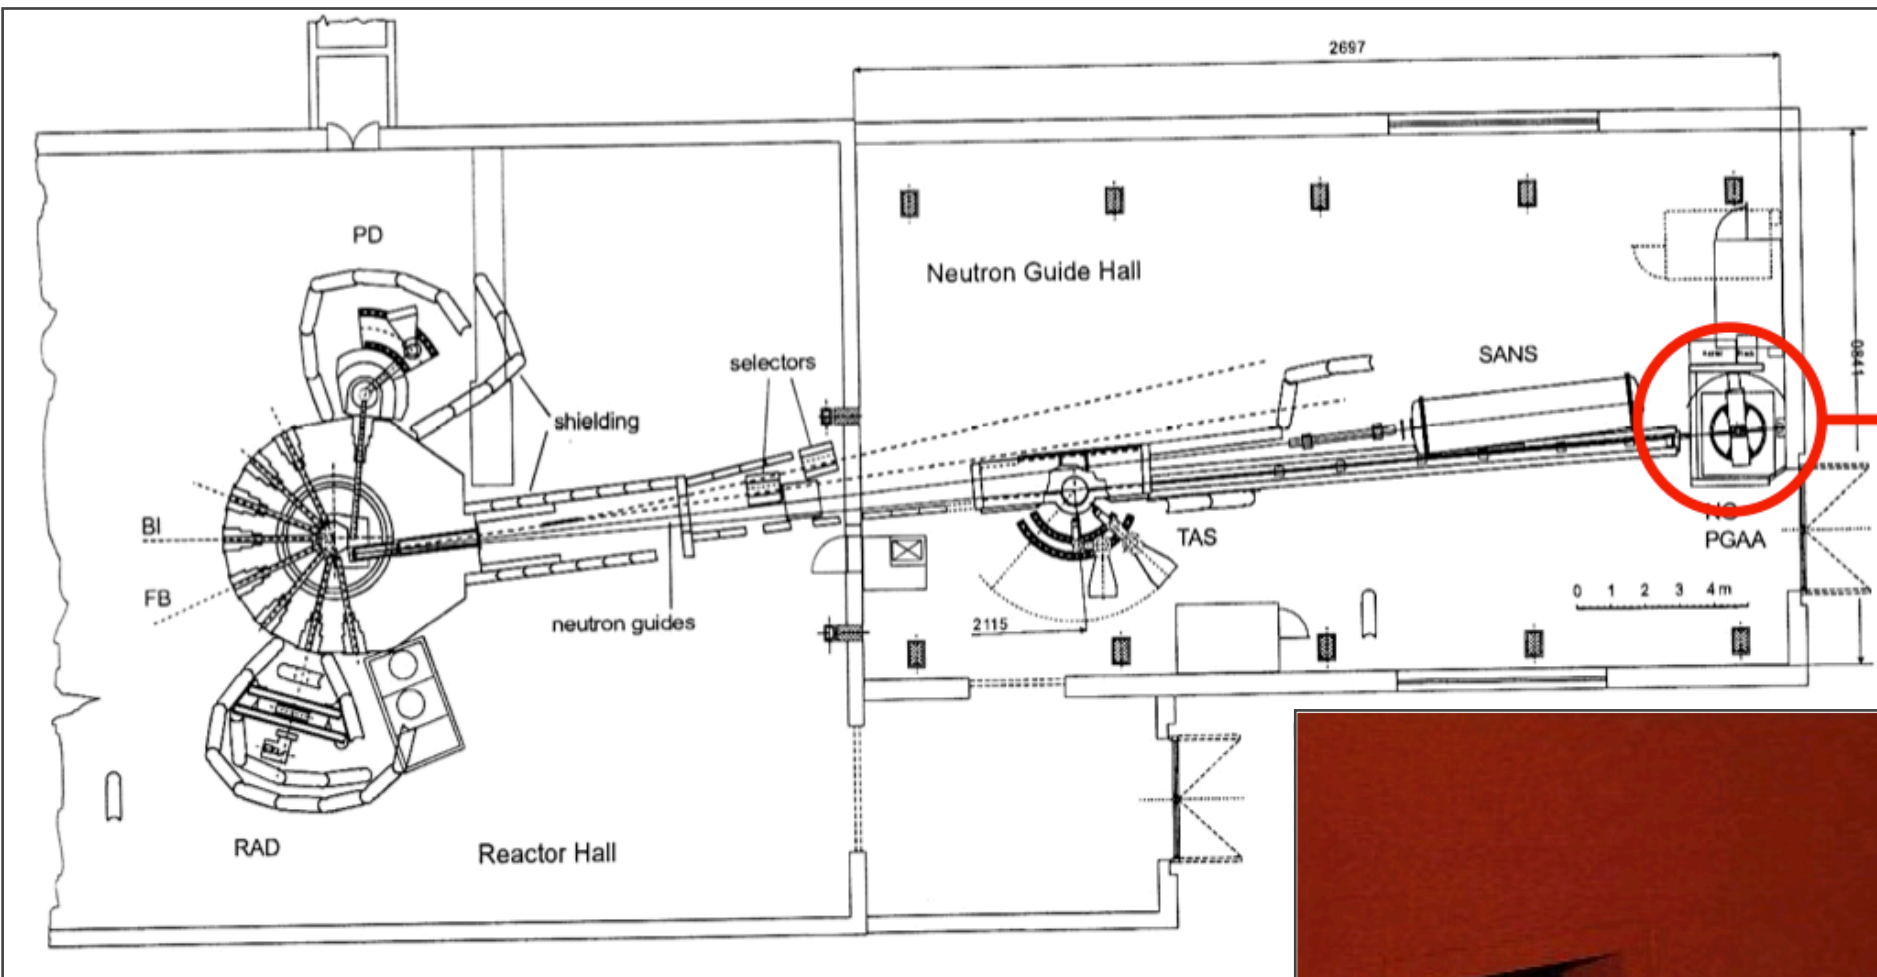

# Experimental setup - beamline

# Experimental setup - beamline

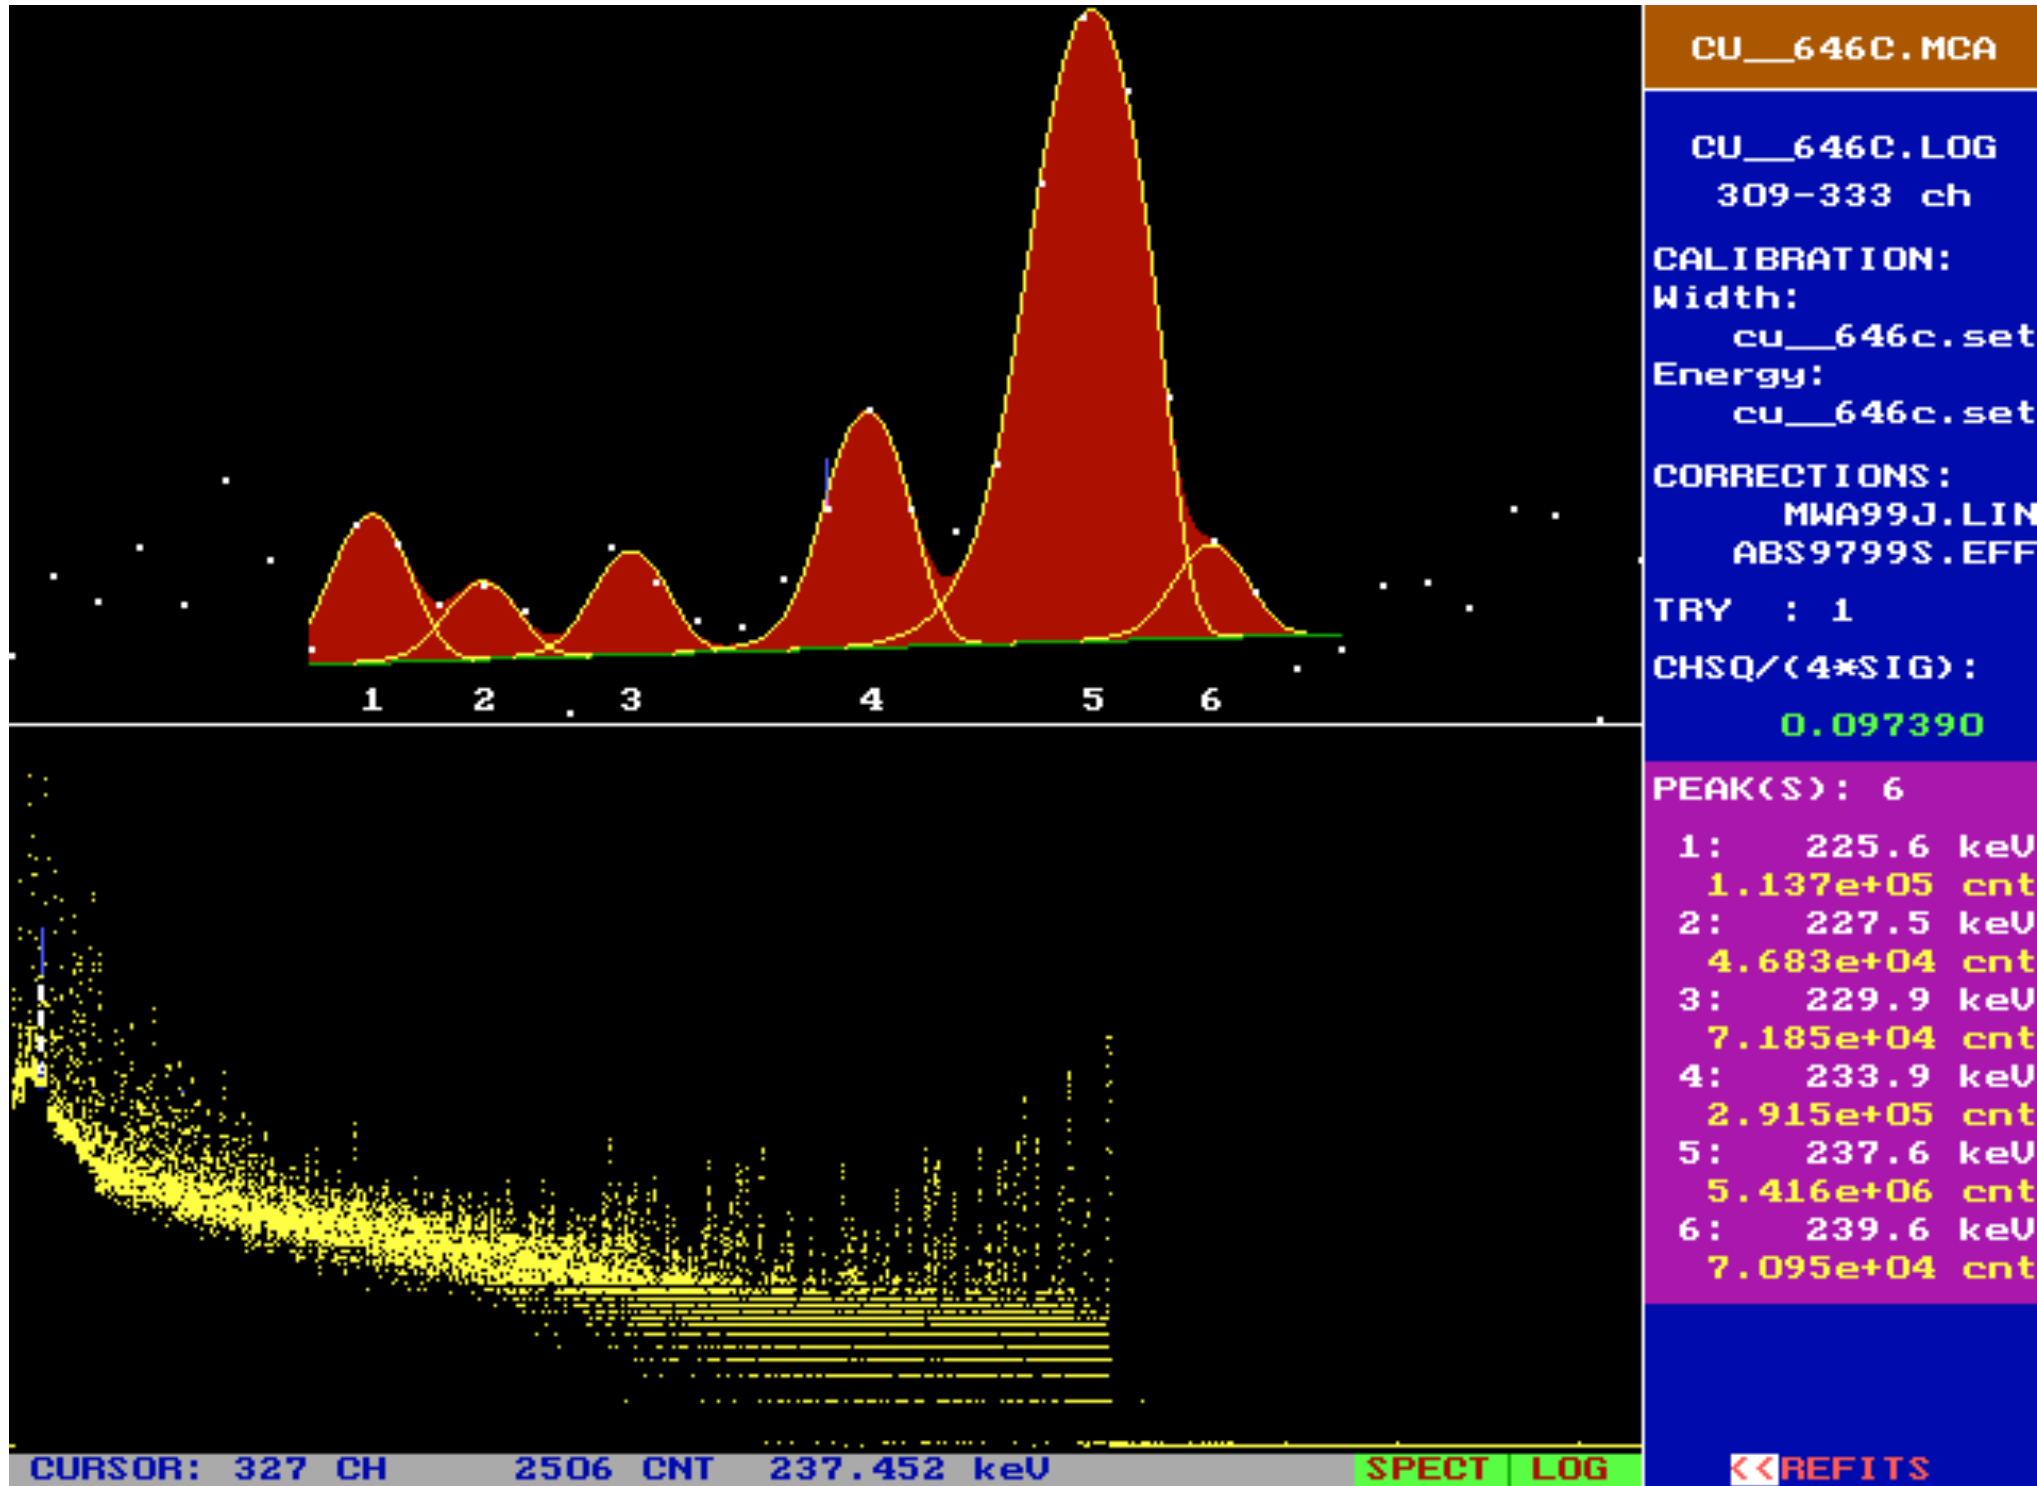

- Experimental setup is located ~35 m from the reactor wall.
- HpGe detector (closed-end coaxial) located ~23 cm from target.
- Compton-suppressed, shielded with BGO detectors.

# Copper ( $n, \gamma$ ) thermal-capture spectrum

# $^{66}\text{Cu}$ ENSDF level scheme

- Last evaluation done in 2009.
- Low-lying 2<sup>nd</sup> excited state at 238 keV has unknown  $J^\pi$ .
- Total thermal-neutron capture cross section (*S.F. Mughabghab 2006*)  
 $\sigma_0 = 2.17 \pm 0.03$  b  
 $S_n = 7066.7 \pm 0.8$  keV
- $^{65}\text{Cu}$  spin state 3/2<sup>-</sup>
- RIPL:  $E_{\text{crit}} = 186$  keV

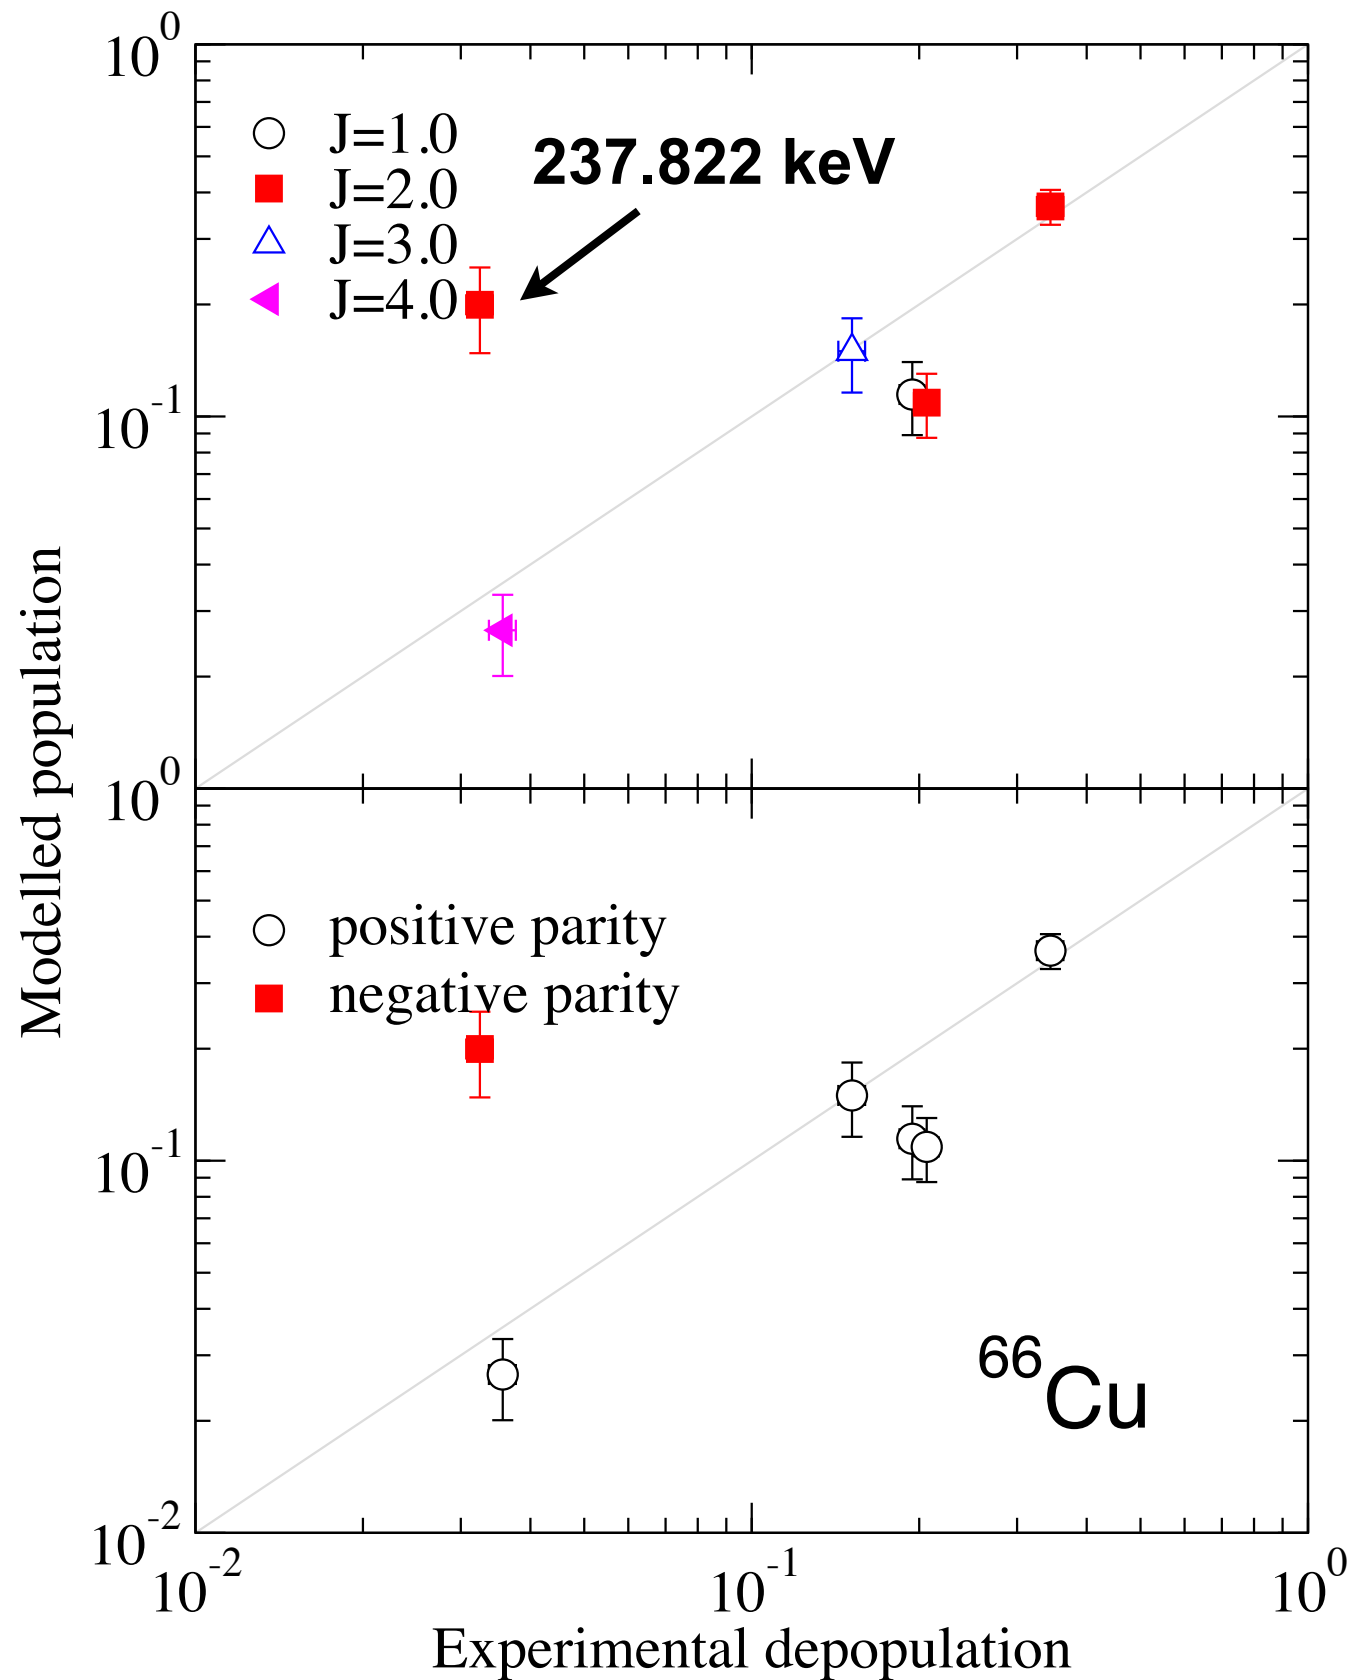

# $^{66}\text{Cu}$ DICEBOX: ENSDF and RIPL

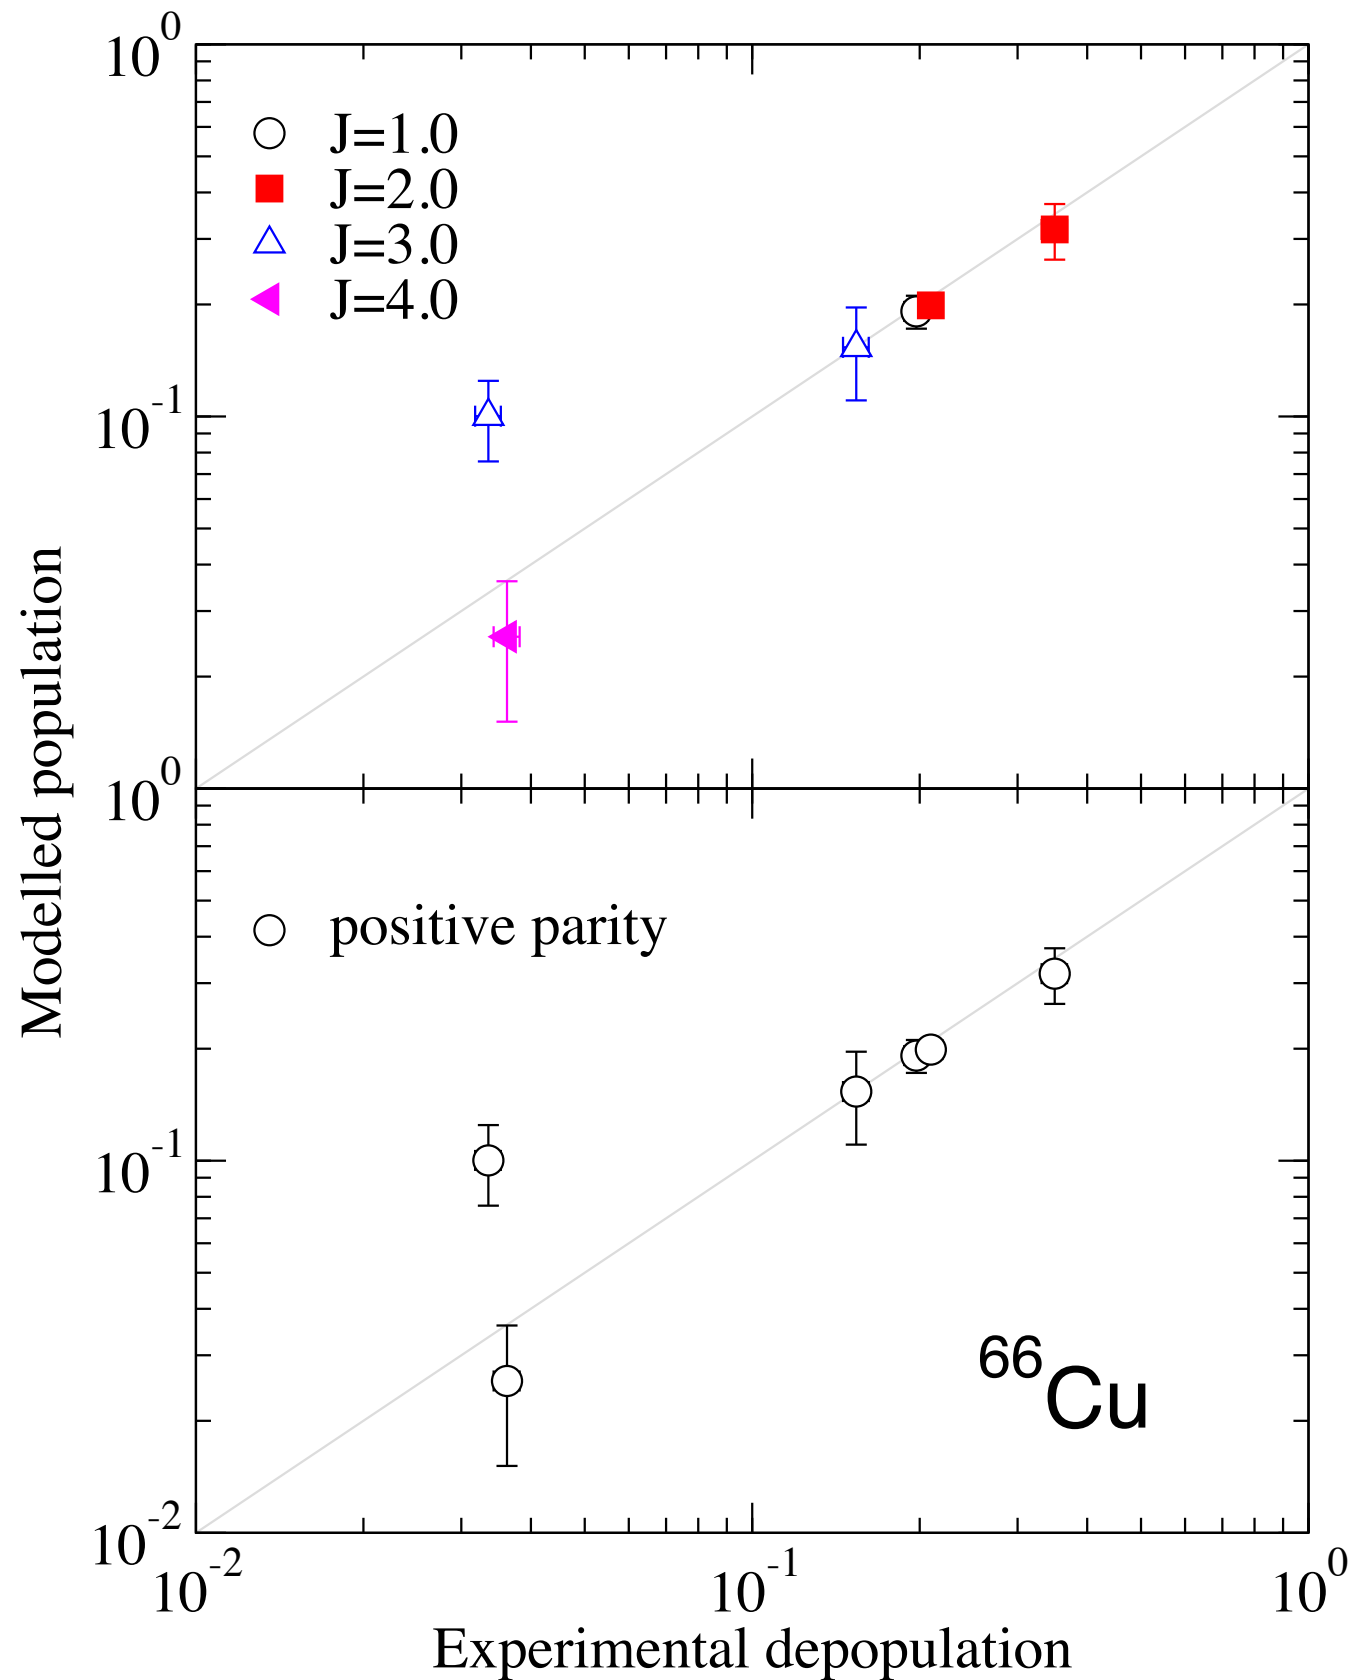

- Included 22 levels
- $E_{\text{crit}} = 1547.39 \text{ keV}$
- Poorly reproduces the DICEBOX calculations.
- Total-capture cross section  
 $\sigma_0 = 2.19 \pm 0.05 \text{ b}$

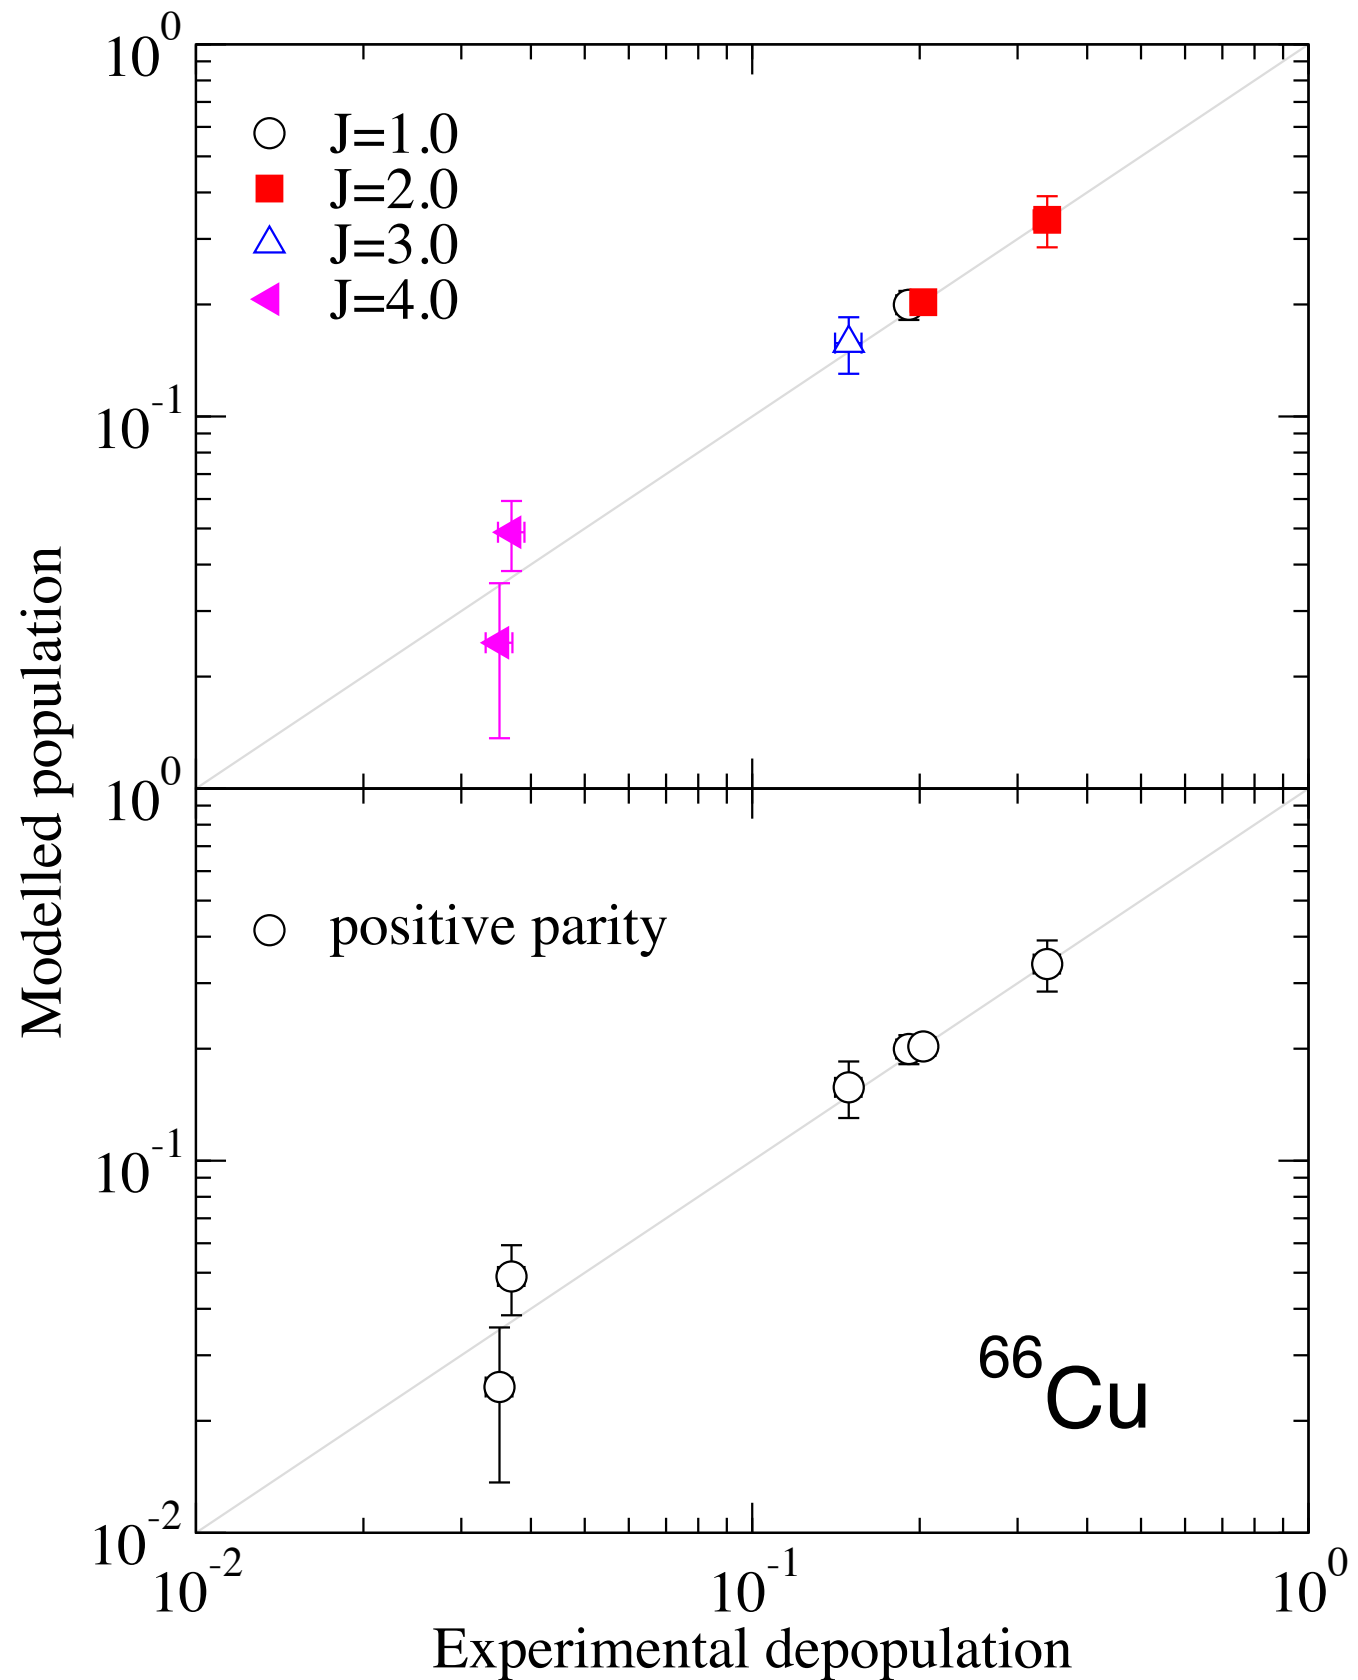

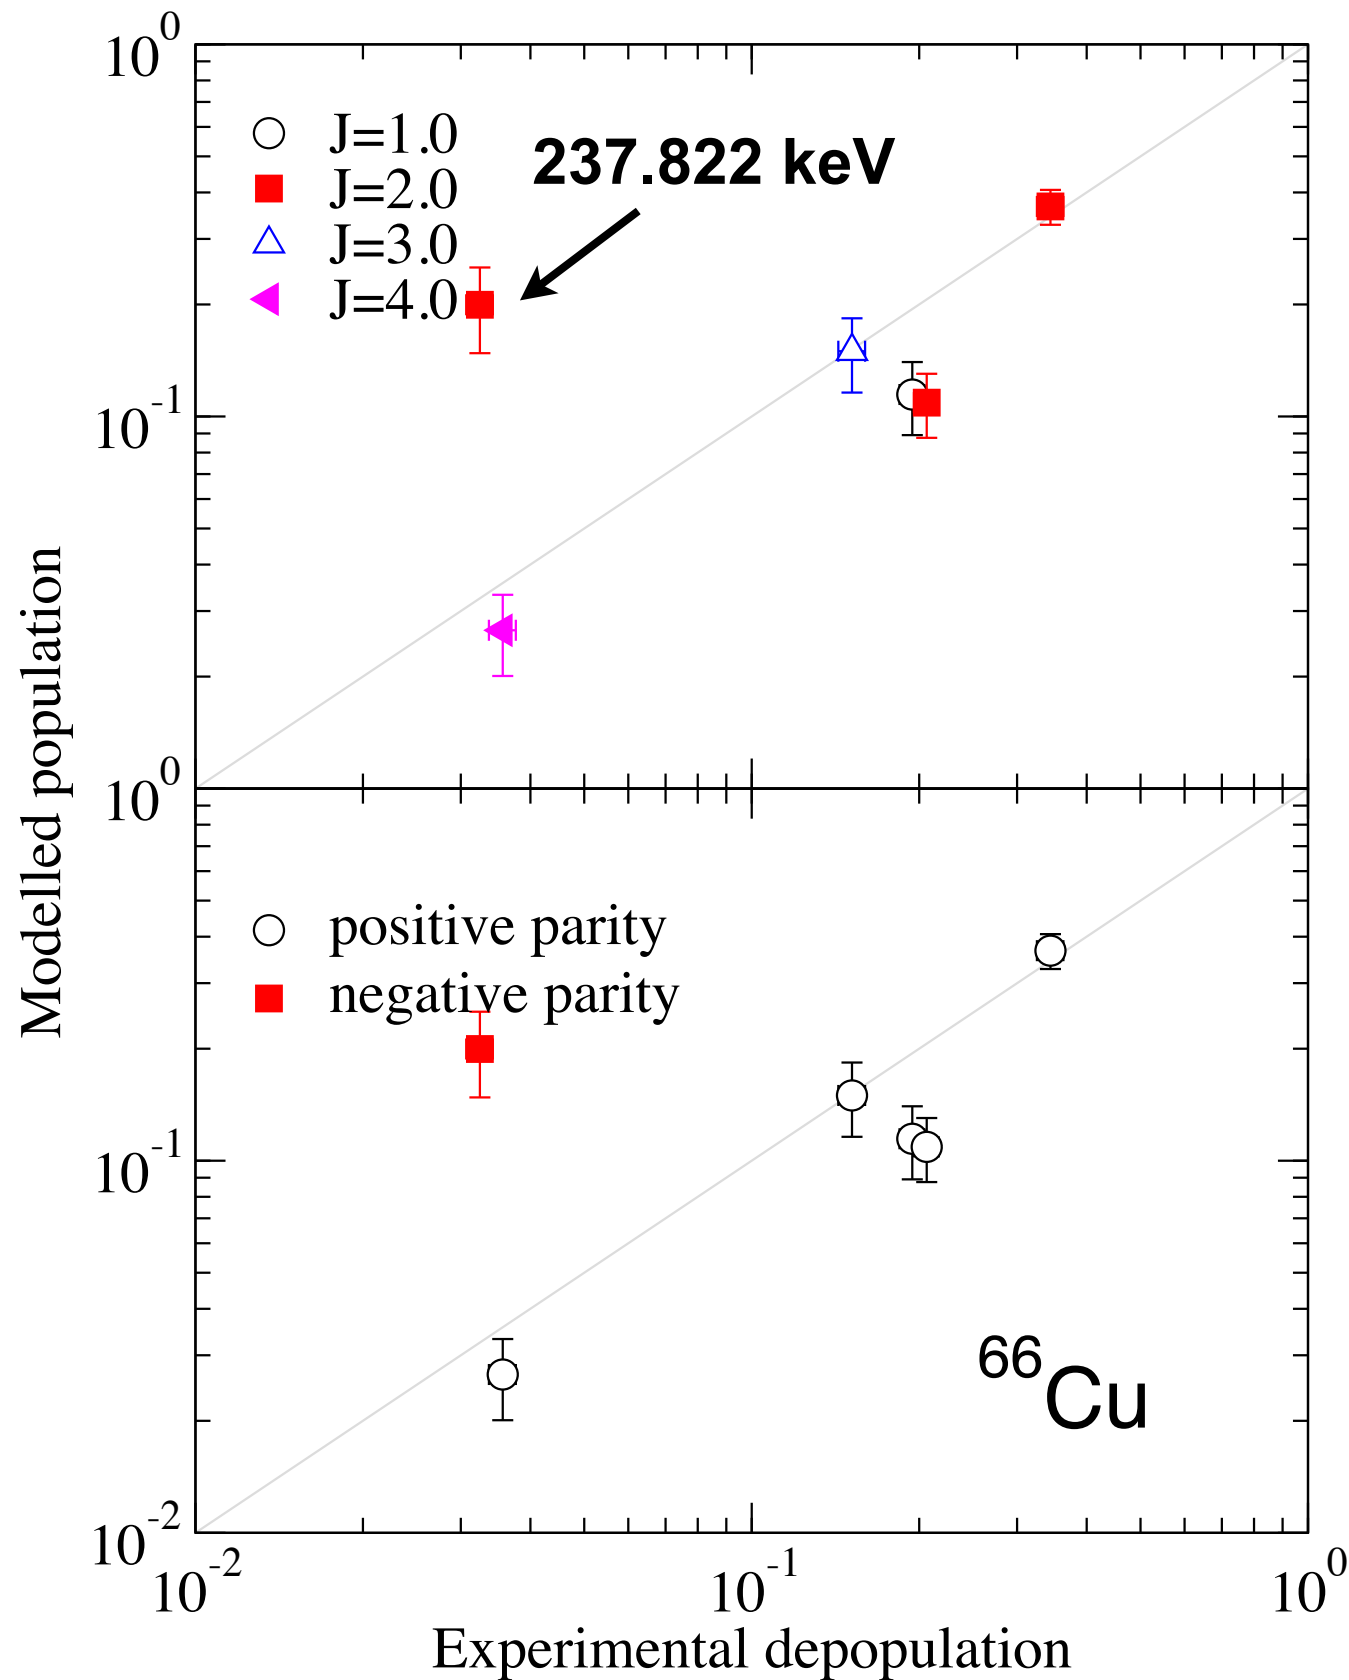

# $^{66}\text{Cu}$ DICEBOX: $E_{\text{crit}} = 591 \text{ keV}$

# $^{66}\text{Cu}$ DICEBOX: $E_{\text{crit}} = 591 \text{ keV}$

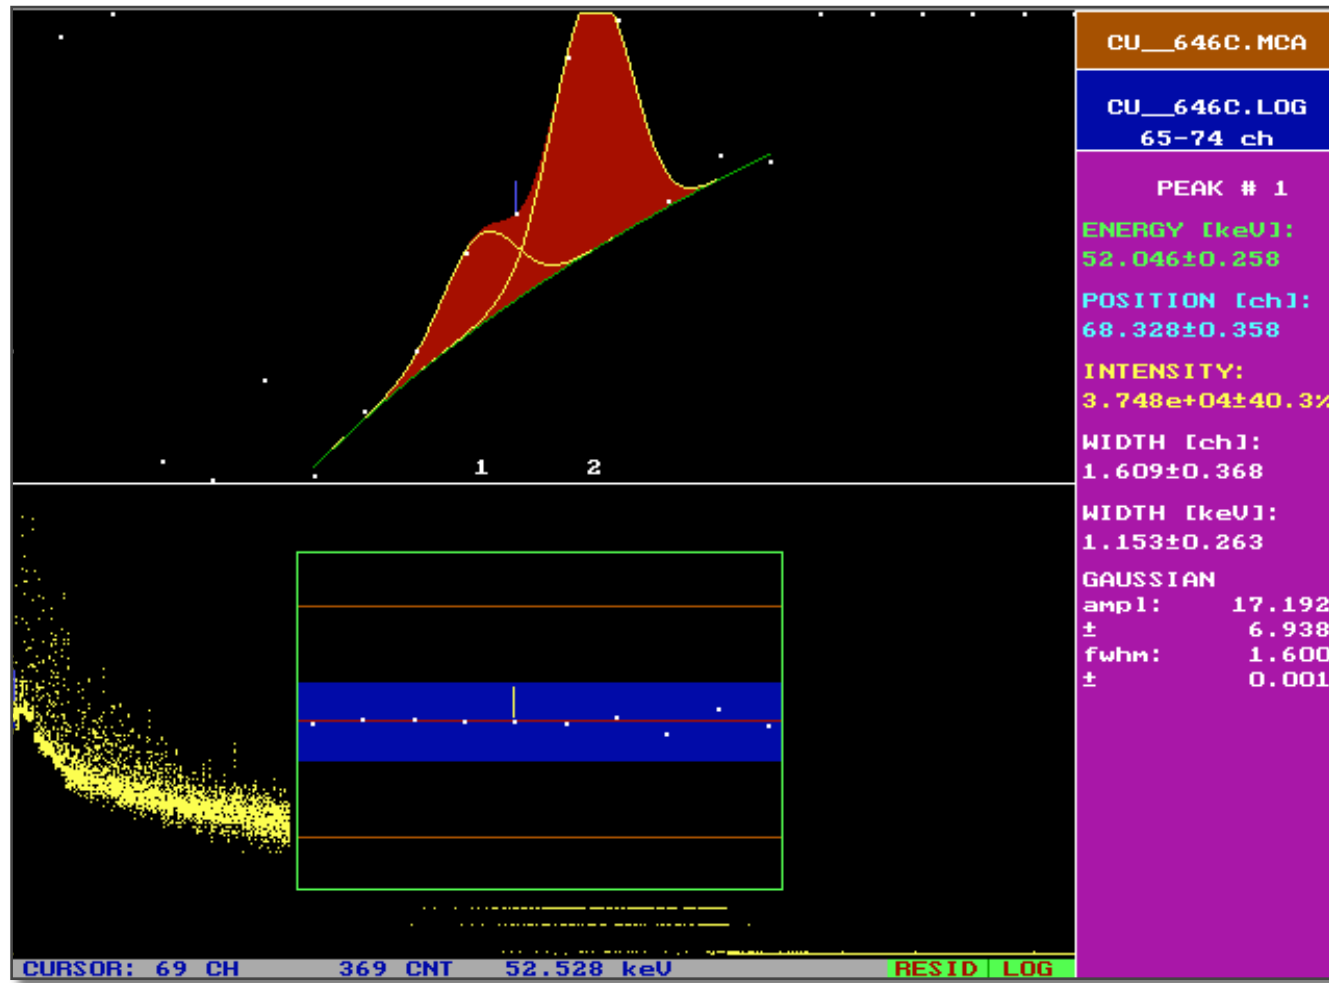

# $^{66}\text{Cu}$ DICEBOX: $E_{\text{crit}} = 591 \text{ keV}$

# $^{66}\text{Cu}$ DICEBOX results

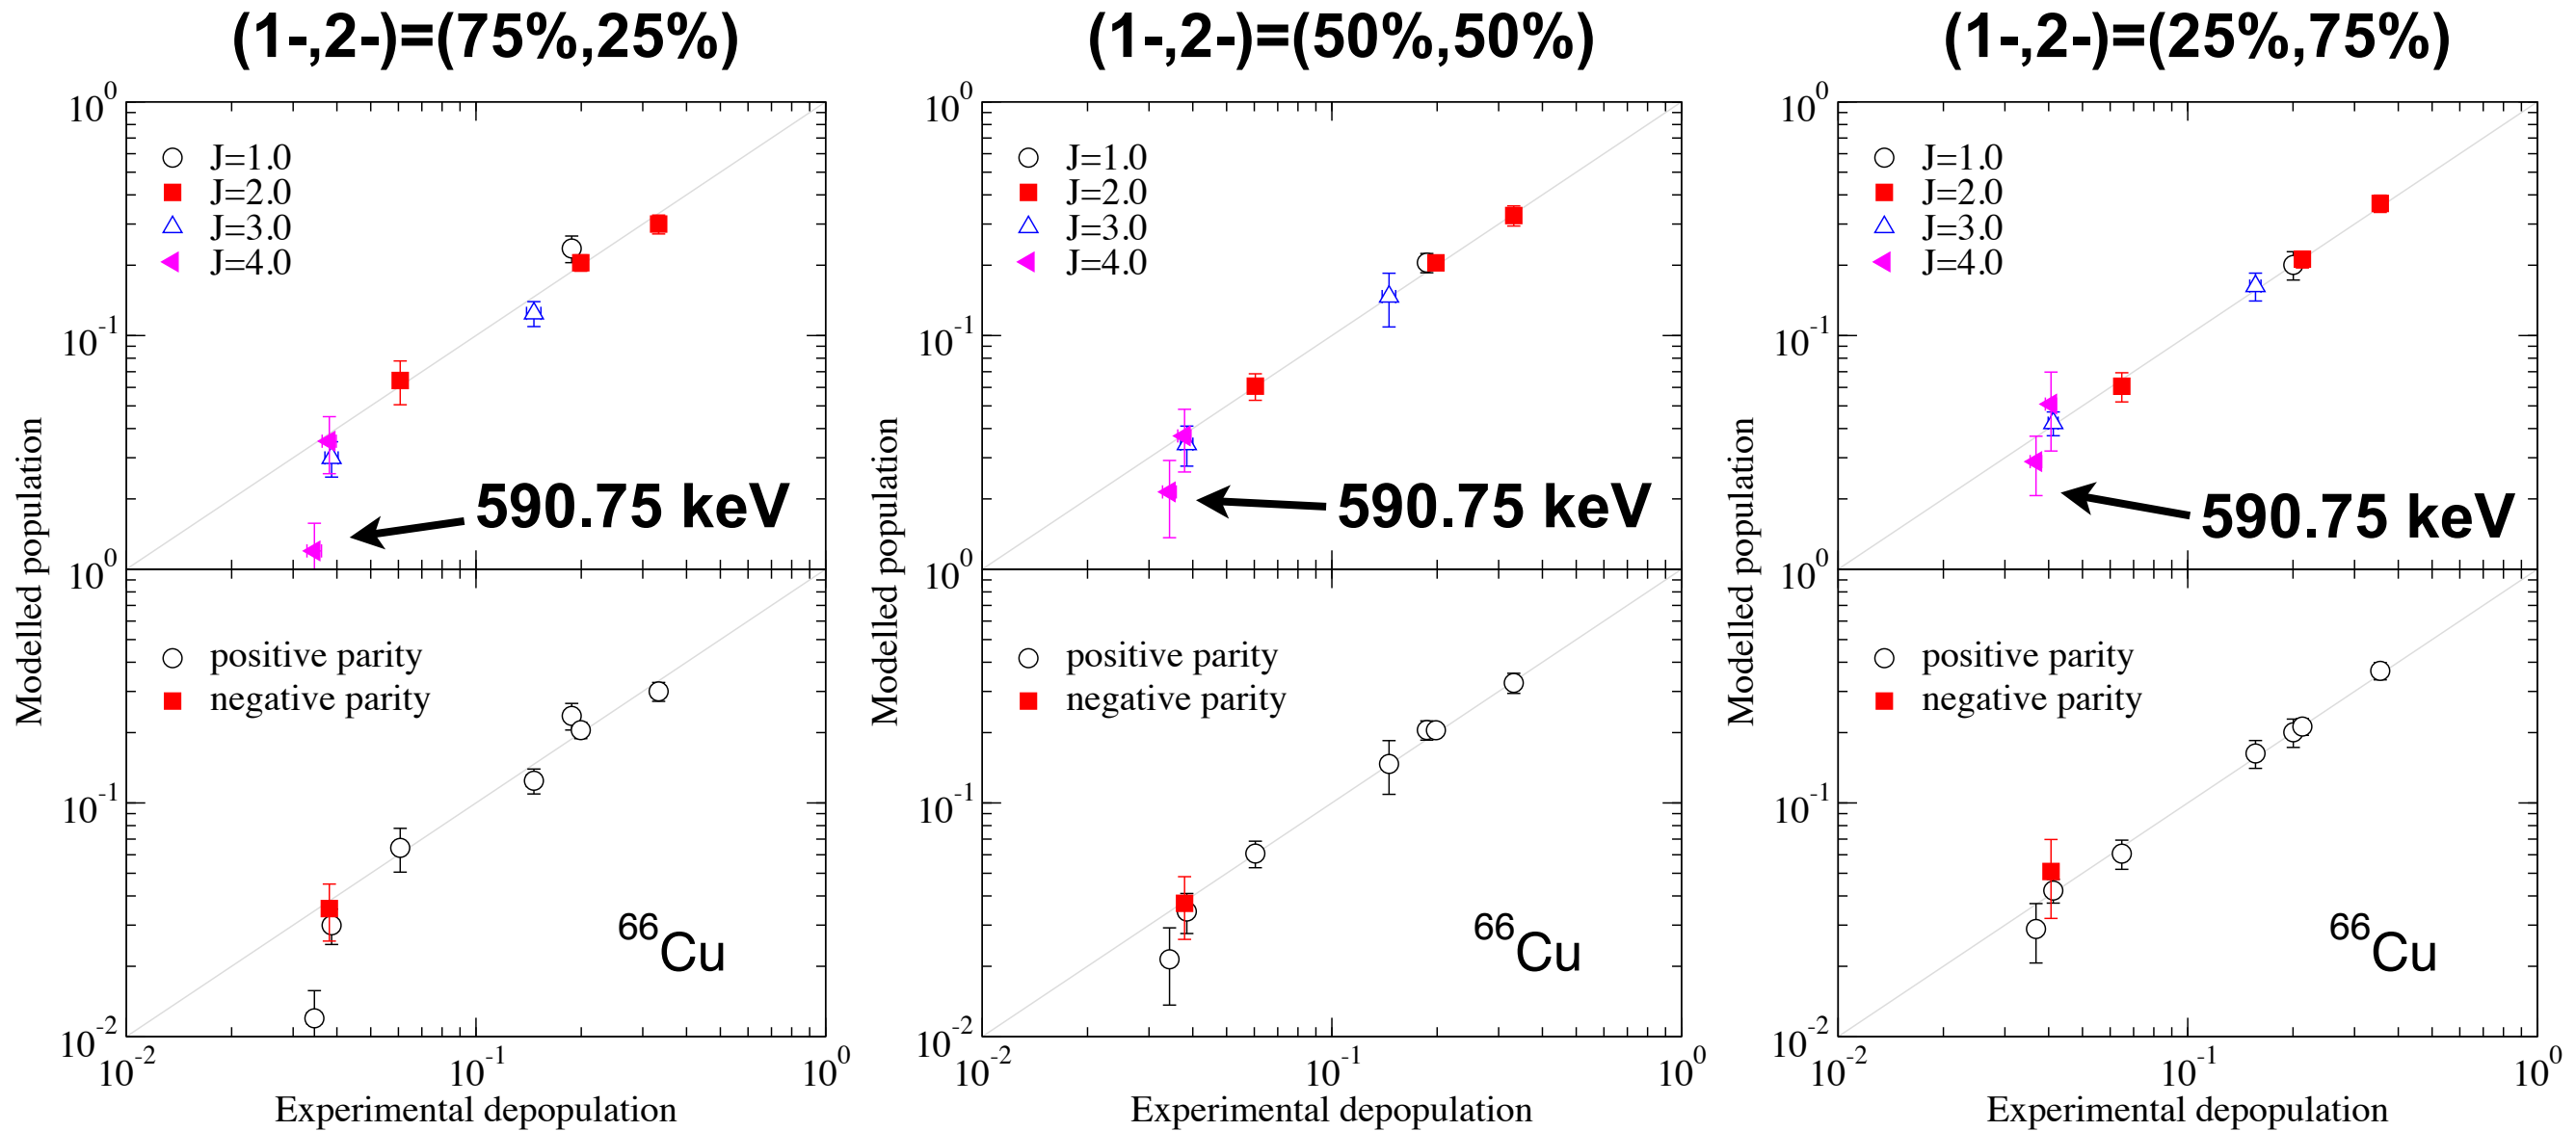

- Included 10 levels
- $E_{\text{crit}} = 822.691$  keV
- Indications of a new transition at 52 keV?
- $\sigma_0 = 2.20 \pm 0.09$  b ( **$2.17 \pm 0.03$  b**)

# $^{66}\text{Cu}$ DICEBOX results

- Included 10 levels
- $E_{\text{crit}} = 822.691$  keV
- Indications of a new transition at 52 keV?
- $\sigma_0 = 2.20 \pm 0.09$  b ( **$2.17 \pm 0.03$  b**)

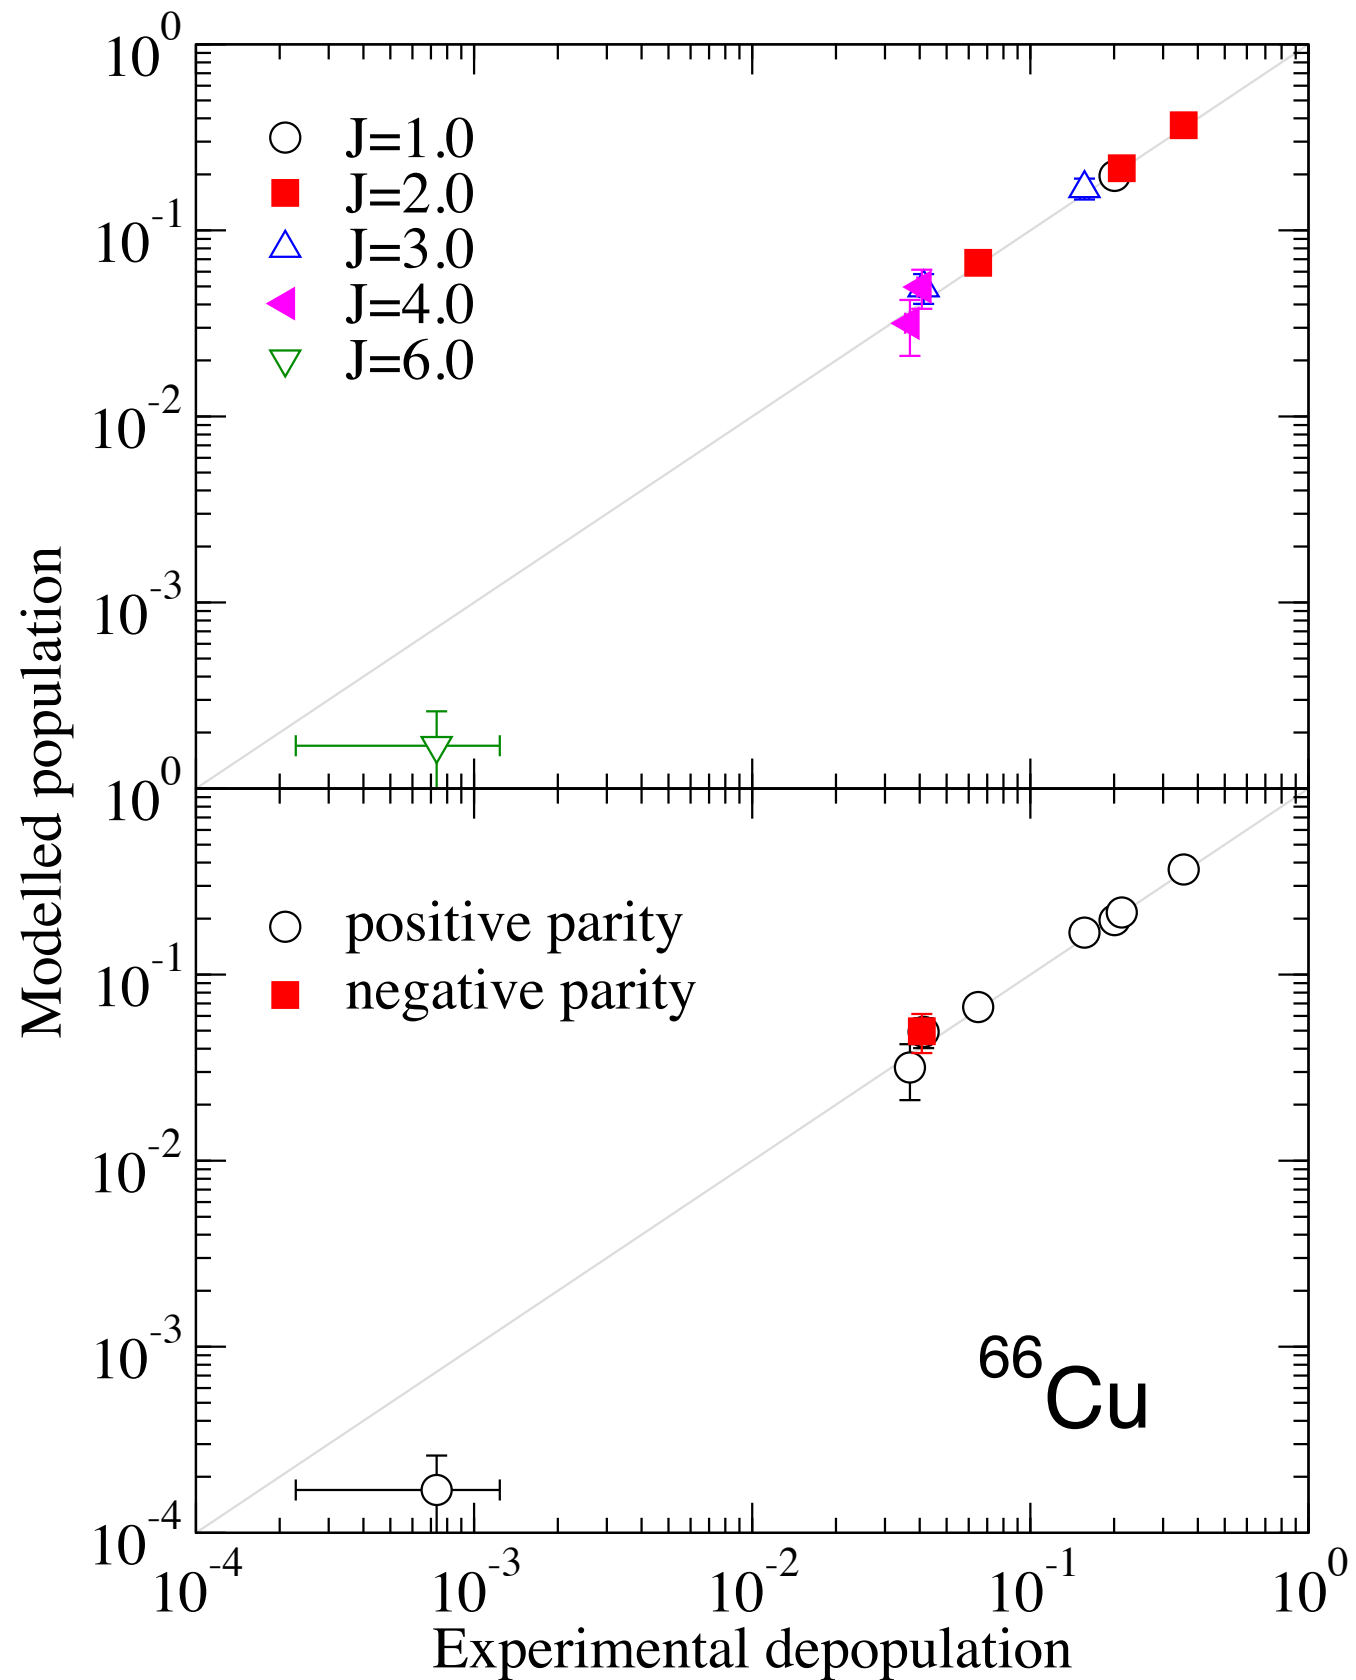

# $^{66}\text{Cu}$ DICEBOX capture-state spin fraction

- Consistent with a dominant  $J^\pi=2^-$  (99%) capture state fraction.
- In agreement with thermal neutron-capture measurements of *M.G. Delfini et al. Nuclear Physics A404 (1983)*

# $^{66}\text{Cu}$ DICEBOX results: $E_{\text{crit}} = 1009 \text{ keV}$

# Summary and outlook

---

- Low-lying 2<sup>nd</sup> excited state is consistent with a spin assignment of  $J=4$ .
- 386-keV excited state tentative 1<sup>+</sup> assignment.
- Consistency between the experimental data and simulated cascades for  $E_{\text{crit}} = 823$  keV and possibly raised to 1009 keV.
- Good agreement of total thermal capture cross section with previous measurements.

$$\sigma_0 = 2.20 \pm 0.09 \text{ b } \mathbf{(2.17 \pm 0.03 \text{ b})}$$

- Explore the effects of additional models and parameters.
- Continue analysis for  ${}^{63}\text{Cu}(n,\gamma){}^{64}\text{Cu}$
