LAPH: A MULTIGROUP PHOTON PRODUCTION MATRIX AND SOURCE VECTOR CODE FOR ENDF/B

by

Donald J. Dudziak, Alan H. Marshall, and Robert E. Seamon

ABSTRACT

The LAPH code retrieves photon production cross sections or photon production multiplicities and corresponding neutron interaction cross sections from ENDF/B (Evaluated Nuclear Data File/B). It then applies suitable weighting functions over G specified photon groups and N specified neutron broad groups to construct a G x N photon production matrix. Pointwise cross sections are first integrated over each photon energy group with constant or direct energy weighting, and then over each neutron fine group with constant weighting. Within each neutron broad group, arbitrary fine-group weighting functions are read from input. Resonance fine-group interaction cross sections and weighting functions are also read as input; at the Los Alamos Scientific Laboratory (LASL), these cross sections and weights are produced directly by a modification of the MC^2 code. Macroscopic photon production and photon energy production matrices are then computed. As an option, spatially dependent photon source vectors for transport calculations can be generated by using input scalar neutron flux vectors. Multiple zones can be accommodated with separate weighting functions for each zone. Different materials and reaction types for which photon production matrices are desired can be specified for each zone. Input is in DTF-IV format, and output photon source vectors are also in this format. A sample problem is included along with an indexed listing of the code. The code is written in FORTRAN IV for a CDC-6600 computer with a $65k_{10}$ memory.

I. INTRODUCTION AND SUMMARY

A national neutron data file now exists at the National Neutron Cross Section Center, Brookhaven National Laboratory, in a single format.[1,2] The file, called the Evaluated Nuclear Data File/B (ENDF/B), contains primarily neutron interaction cross sections, angular distributions, secondary energy distributions, thermal scattering laws, and other data of interest in reactor core neutronics analysis. Recently, however, with the expansion of the ENDF/B format to provide for photon production and photon interaction data,[2] the file is becoming increasingly important and useful in shield analysis and design. Included in the shielding interests are weapons and civil defense problems, as well as reactor shielding.

The ENDF/B data file is of real significance only when considered as part of what will be called the "ENDF/B system," which consists of not only the data file but also the data retrieval, checking, and processing codes. For neutron interaction data (ENDF/B Files 2 through 7), such codes are presently available in varying degrees of development, and the data are actually being extracted for use in neutronics calculations, such as transport, thermalization, and fast spectra problems. The photon files (14 through 16 and 23 through 27), however, are in their infancy with evaluated photon production data for only six materials[3,4] (sodium, magnesium, silicon, chlorine, potassium, and calcium) presently available in the ENDF/B format, and even these data have not been through a complete data testing procedure. Because of this, the publicly

released ENDF/B data file of 1969 contained no photon production data. One obvious requirement for checking the photon data in an integral manner, as well as a clear incentive for evaluators to place these data in the file, is to have a code to retrieve the data in a usable form for multigroup photon transport calculations. These are two motivations for the LAPH code.

Throughout this report, it is assumed that the reader is familiar with the ENDF/B system, since LAPH operates only within that system. Detailed descriptions of the data formats are given in the references cited above, and a review of the storage and retrieval of photon data in the ENDF/B system has been presented elsewhere.[5] Pertinent format information will be reviewed here as required, however.

Briefly, the LAPH code retrieves photon production cross sections or multiplicities and corresponding neutron interaction cross sections from the ENDF/B data file, applies suitable weighting functions over N specified neutron groups and G specified photon groups, and constructs a G x N photon production matrix. As an option, it operates on this matrix with flux vectors from a neutronics code, as well as with scalar multipliers such as atom number densities and effective photon group energies, to directly provide spatially dependent photon source terms for transport calculations. Figure 1 presents a schematic description of the code, where the input data are left of the dotted line. This schematic diagram is not intended to present the detailed logic of the code, which is given in Appendices A and B.

II. THEORY

A. Photon Production Data Format in ENDF/B

To understand the process of computing photon production matrices and photon source functions from the ENDF/B data file (the process is loosely called "theory"), it is helpful to review the form in which the data are received into LAPH; i.e., the form in which they are stored in the ENDF/B data file. Photon multiplicities are entered into ENDF/B File 15 in one of two options,[2] either directly in a manner analogous to File 5 or as transition probability arrays.

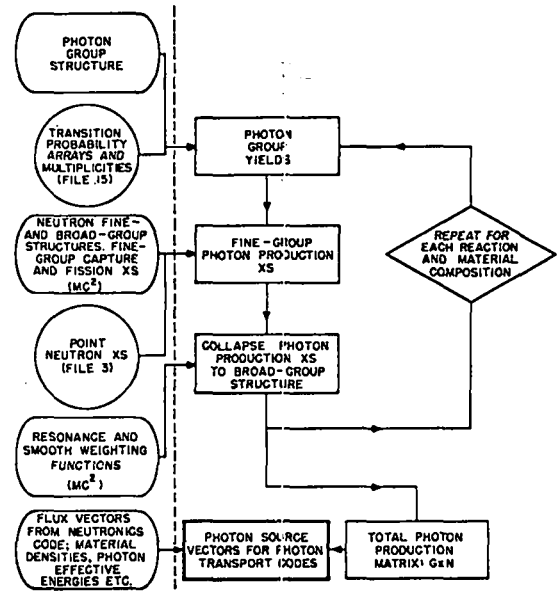

Fig. 1. LAPH code schematic.

Under Option 1 of File 15, the multiplicities are given by a normalized photon energy distribution and an associated total photon yield (units of photons) for an interaction. Normalized photon energy distributions are given according to allowable laws, of which two are presently instituted: viz., (Law 1) a tabulated probability density function vs photon energy, or (Law 2) a Dirac delta function in photon energy. In addition, the tabulated function (Law 1) is a function of incident neutron energy; hence, a two-dimensional table is used for tabulated probability functions. For either law, the yields are tabulated functions of incident neutron energy. New laws may be added later when deemed necessary; e.g., a normalized prompt fission-gamma spectrum may be useful.

For Option 2, a level is identified by a level sequence number and level energy. The only additional data (other than a few control parameters) needed to specify the photon energies and yields are (1) the nonzero transition probabilities to lower levels, (2) the gamma transition conditional probabilities if nonunity, and (3) the energies of the lower levels. These data are entered as doublets or triplets for each transition, depending

upon whether or not the conditional probabilities are unity. Thus, processes such as internal conversion can be accounted for very simply. Also, data listed for any level include only those for photons originating at the level. Further cascading is determined from the data for lower levels, so only the minimum required data are stored in the ENDF/B system. The LAPH code reconstructs the cascade.

An important limitation of the transition probability arrays is that they cannot be used to accurately predict photon production by neutrons at energies appreciably above that of the highest level for which the gamma decay scheme is well known. The reason for this is that, at higher energies, levels above the one for which the decay scheme is well known may be excited and cascade through lower levels. Thus, at these higher energies, the photon production must be accounted for under Option 1. In fact, LAPH will not use the transition probability arrays to calculate photon production at neutron (center of mass) energies above the highest level in the arrays; i.e., if ES_{max} is the highest level energy for which a transition probability array is given, no photon production will be calculated from the arrays for incident-neutron energies above $ES_{max} \times \frac{AWR + 1}{AWR}$, where AWR is the atomic weight ratio.

In ENDF/B data files[4] for sodium, magnesium, chlorine, potassium, and calcium (used for debugging purposes), the photon production at these higher energies was placed in a photon production reaction which was assigned MT = 110. A unit cross section was placed in File 3 for MT = 110, and the photon production cross sections (in barns) to produce a discrete photon of a given energy were placed in the yield table of File 15, Option 1, LF = 2.

The units for data stored in the ENDF/B file are:

Quantity	Units
energy	eV
angle	dimensionless cosine
cross section	barns
photon yields	photons

B. Photon Yields and Photon Production Cross Sections

Photon yields are either given directly as a function of neutron energy in Option 1 of File 15 or must be constructed by processing codes (including LAPH) from the transition probability arrays of Option 2. The construction process for a microscopic photon production cross section in the latter case is discussed in Appendix B of Ref. 2 (the general equation on p. 51 of Ref. 2 should have the variable TP substituted for A in all of the summations). For completeness, the discussion will be reviewed. Define

1. $\sigma_{j,i}(E)$ = cross section to produce the photon which arises from decay of level j to i, with incident-neutron energy E.
2. $\sigma_k(E)$ = neutron cross section for inelastic scattering to level k, for incident-neutron energy E.
3. $TP_{j,i}$ = probability of a direct transition from level j to level i, i < j.
4. $GP_{j,i}$ = conditional probability of photon emission in a direct transition from level j to level i, i < j.
5. $A_{j,i} = (TP_{j,i})(GP_{j,i})$.
6. ES_i = energy of level i.

Note that the photon production cross section is given for transition between specific levels, which implicitly determines the photon energy, rather than for a given photon energy. This scheme avoids ambiguity when two different transitions produce photons of the same energy. The photon energy is simply $E_\gamma = ES_j - ES_i$.

For the general case, all possible transitions must be considered, as well as the possibility of transitions not involving gamma-ray emission. Accounting for all possibilities leads to the expression given in Ref. 2, p. 51, viz.,

$$\sigma_{j,i}(E) = A_{j,i} \sum_{m_o=j}^{N} \sigma_{m_o} \overbrace{\left| \right|}^{n+1}_{\ell=1} \sum_{m_\ell=j}^{m_{\ell-1}-1} TP_{m_{\ell-1},m_\ell} , \quad (1)$$

where N = highest level such that $ES_N \leq E \frac{AWR}{AWR + 1}$. The requirement that $m_n \leq j + 1$ determines the range of the index n, and $(m_{\ell-1} - 1) > j$ is implicit.

This pointwise photon production cross section can then be written in the notation of Ref. 2 as $\sigma(E_\gamma \leftarrow E)$ for discrete photon energy $E_\gamma = ES_j - ES_i$. Recall that this construction scheme using Option 2 of File 15 does not apply at incident neutron energies $E > ES_{max} \times \frac{AWR + 1}{AWR}$. The energy ES_{max} is found by searching for the largest MT number in the set $\{5 \leq MT \leq 14 \text{ or } 51 \leq MT \leq 80\}$, and reading ES for that MT value.

Under Option 1 of File 15, the photon yield functions are first constructed from the tabulated yield at incident-neutron energy E, and a normalized photon energy distribution (which may be delta function in E_γ). These two components can be given for different photon distribution laws as subsections of one reaction type (MT number). Specifically, if $y_k(E)$ is the yield from subsection k, and $f_k(E_\gamma \leftarrow E)$ is the corresponding normalized photon energy distribution, the yield function is given by

$$y(E_\gamma \leftarrow E) = \sum_{k=1}^{NK} y_k(E)\ f_k(E_\gamma \leftarrow E) \qquad (2)$$

(photons/eV).

The $y_k(E)$ have units of photons, and the $f_k(E_\gamma \leftarrow E)$ have units of eV^{-1}. Having the yield function, the pointwise differential photon production cross section is determined as

$$\frac{d\sigma(E_\gamma \leftarrow E)}{dE_\gamma} = \sigma(E)\ y(E_\gamma \leftarrow E) \qquad (3)$$

(b-photons/eV),

where $\sigma(E)$ is the interaction cross section for the appropriate reaction type from Files 2 and 3.

Once the differential photon production cross sections are determined, they are integrated over arbitrary neutron and photon energy groups, with selected appropriate weighting functions, to determine a photon production cross-section matrix. In the discussion below, the subscripts and superscripts are defined as follows:

g = photon energy group, g = 1,2,...,G

ℓ = neutron fine group, ℓ = 1,2,...,L

n = neutron broad group, n = 1,2,...,N

k = partial yield index, k = 1,2,...,NK

p = reaction type (MT number)

i = material number

j = zone number, j = 1,2,...,IZM

m = spatial mesh interval, m = 1,2,...,IM

r = resolved resonance component

s = unresolved-resonance and smooth components.

The lower energy limit of a group is denoted by E_g, E_ℓ, or E_n. The indices i and j will be suppressed for a while to avoid too clumsy a notation, but they are implicit.

Two weighting options, called tracks, are available to compute the photon yield in a group, g, as follows:

Track 1 is a constant weighting, i.e.,

$$Y_g^p(E) = \int_{E_g}^{E_{g+1}} dE_\gamma\ Y^p(E_\gamma \leftarrow E) \qquad (4)$$

(photons),

where $Y^p(E_\gamma \leftarrow E)$ may be a Dirac delta function. On this track, the photon group energy yield, $\tilde{Y}_g^p(E)$, is computed by using an arbitrary group effective energy, $\bar{E}_g$, which is an input quantity. However, the code still calculates the energy-weighted yield on Track 2 and provides the user with a listing of the average (yield-weighted) energy, $\hat{E}_g^p$, in each group. In effect, on Track 1, the photon energy yield is

$$\tilde{Y}_g^p(E) = Y_g^p(E)\ \bar{E}_g \qquad (eV). \qquad (5)$$

If a value of $\bar{E}_g$ is not in the interval $[E_g, E_{g+1}]$, the code will assume the median group energy, $\bar{E}_g = \frac{1}{2}(E_g + E_{g+1})$, and proceed with this calculated value vice the input value.

Track 2 is an energy-weighted yield, i.e.,

$$\tilde{Y}_g^p(E) = \int_{E_g}^{E_{g+1}} dE_\gamma\ Y^p(E_\gamma \leftarrow E)\ E_\gamma \qquad (eV), \quad (6)$$

and

$$Y_g^p(E) = 2\left[\tilde{Y}_g^p(E)\right]\left[E_{g+1} + E_g\right]^{-1} \qquad (7)$$

(photons).

The calculation in Eq. 6 is also performed on Track 1, where the average energy in each group is computed by

$$\hat{E}_g^p = \frac{\int_{E_g}^{E_{g+1}} dE_\gamma \, Y^p(E_\gamma \leftarrow E) \, E_\gamma}{\int_{E_g}^{E_{g+1}} dE_\gamma \, Y^p(E_\gamma \leftarrow E)} \quad \text{(eV)}. \quad (8)$$

The photon energy group structure is arbitrary, and is specified by an input energy mesh, starting at the highest energy. Likewise, the neutron energy group structures are arbitrary, except that the fine-group energy mesh points must have the broad-group mesh points as a subset. In practice, the neutron group structures are usually the corresponding structures in a spectrum-averaging code such as MC^2. In fact, a version of the MC^2 code[6] has been modified to output pertinent portions of the LAPH input. The photon energy mesh for the integrations on Tracks 1 and 2 is the overlay of the photon group energy mesh and the E_γ mesh for the $f_k(E_\gamma \leftarrow E)$ in File 15. The simple trapezoidal rule is used for the integration. The $Y_g^p(E)$ are evaluated at every tabulated neutron energy in File 15.

There is one approximation inherent in using data for a continuous photon spectrum. For any incident-neutron energy E, between two neutron energies E_1 and E_2 at which photon energy distributions are tabulated, there may be a component of the photon distribution up to energy $E_2 + Q$. Here, Q has its usual meaning--the reaction energy. Thus, photons can be constructed at energies greater than E + Q (the theoretical maximum) from this interpolated energy distribution. This problem occurs for any interpolation scheme between incident-neutron energies, and minimizing the induced error depends upon the evaluator having entered the data in the ENDF/B file with a fine enough incident-neutron energy mesh. (The same problem occurs for secondary neutron distributions in ENDF/B File 5.)

Having averaged the yields over each photon group, the averaging over each neutron fine group proceeds along one of two tracks. The track used is determined by a combination of the reaction type (MT) number and by an input option. Briefly, for fission and capture (MT = 18 and = 102), respectively, the cross-section averaging over a neutron fine group may be performed in the resonance region by a spectrum-averaging code, or the resonance parameters may be ignored (or be nonexistent) and all cross-section averaging will be done internally by LAPH.

Track A, which is always used except possibly for fission and capture, uses a constant weighting over a neutron fine group to calculate the photon production cross section, $\tau_{g,\ell}^p$, as follows:

$$\tau_{g,\ell}^p = (\Delta E_\ell)^{-1} \int_{E_\ell}^{E_{\ell+1}} dE \, \sigma^p(E) \, Y_g^p(E) \quad \text{(b-photons)}, \quad (9)$$

where $\Delta E_\ell = E_{\ell+1} - E_\ell$, and $\sigma^p(E)$ is the neutron interaction cross section for reaction type p (from ENDF/B File 3). The photon energy production cross section is, similarly,

$$\tilde{\tau}_{g,\ell}^p = (\Delta E_\ell)^{-1} \int_{E_\ell}^{E_{\ell+1}} dE \, \sigma^p(E) \, \bar{Y}_g^p(E) \quad \text{(b-eV)}. \quad (10)$$

Track B, which is used only for fission and capture and only then if this track is chosen by the input option, uses input values of the cross section averaged over the neutron fine group, as follows:

$$\rho_{g,\ell}^{p,r} = (\Delta E_\ell)^{-1} \, \overline{\sigma}_\ell^{p,r} \int_{E_\ell}^{E_{\ell+1}} dE \, Y_g^p(E)$$

$$\rho_{g,\ell}^{p,s} = (\Delta E_\ell)^{-1} \, \overline{\sigma}_\ell^{p,s} \int_{E_\ell}^{E_{\ell+1}} dE \, Y_g^p(E) \quad \text{(b-photons)}, \quad (11)$$

where p = 18 or = 102. Here $\overline{\sigma}_\ell^p$ is the cross section averaged over group ℓ by a spectrum-averaging code, while $\rho_{g,\ell}^p$ denotes the photon production cross section (resonance, or smooth plus unresolved resonance). Similarly,

$$\tilde{\rho}_{g,\ell}^{p,r} = (\Delta E_\ell)^{-1} \, \overline{\sigma}_\ell^{p,r} \int_{E_\ell}^{E_{\ell+1}} dE \, \bar{Y}_g^p(E)$$

$$\tilde{\rho}_{g,\ell}^{p,s} = (\Delta E_\ell)^{-1} \, \overline{\sigma}_\ell^{p,s} \int_{E_\ell}^{E_{\ell+1}} dE \, \bar{Y}_g^p(E) \quad \text{(b-eV)}. \quad (12)$$

This track normally would not be used, for example, if resonance data were not given in ENDF/B File 2 for the materials considered. If it is used, it must be used over the entire neutron energy range, i.e., both tracks cannot be used for a given reaction. Also, the same track must be used for both fission and capture.

The above integrations on Tracks A and B are performed by the trapezoidal rule, using a mesh determined by the overlay of the fine-group energy mesh and the cross-section mesh in File 3.

Having computed the photon production cross-section elements for the neutron fine-group structure, it remains to find a weighted average over the broad groups. These broad groups would normally correspond to the groups used in a neutron transport calculation from which the fluxes are obtained for use in determining the photon source. Weighting of the fine-group photon production cross sections is done with arbitrary sets of input weights, one set for the smooth cross sections and one for the resonance cross sections. The latter set, of course, is used only if Track B is chosen. In practice, the smooth cross-section weights are usually the fine-group fluxes from an infinite medium (zero-dimensional), one-dimensional, or other appropriate spectrum. Also, the resonance weights are usually those from the same spectrum-averaging code. At LASL, both sets of weights are output by the modified MC^2 code referred to above. Denoting the smooth weights by w_ℓ^s and the resonance weights by w_ℓ^r, the elements of the G x N microscopic photon production matrix for reaction type p are

$$\sigma^p_{g,n} = \left[\sum_{\ell\in n} \tau^p_{g,\ell}\, w^s_\ell\right]\left[\sum_{\ell\in n} w^s_\ell\right]^{-1} + \left[\sum_{\ell\in n} \sigma^{p,r}_{g,\ell}\, w^r_\ell\right]\left[\sum_{\ell\in n} w^r_\ell\right]^{-1} + \left[\sum_{\ell\in n} \sigma^{p,s}_{g,\ell}\, w^s_\ell\right]\left[\sum_{\ell\in n} w^s_\ell\right]^{-1}, \qquad (13)$$

and analogous elements $\tilde{\sigma}^p_{g,n}$ for the energy production matrix. In the calculation of $\sigma^p_{g,n}$, the code actually performs the calculation differently from the direct way shown in Eq. (13) by normalizing the weights ahead of time.

Though it is not explicitly indicated in the notation, these cross sections are determined by LAPH for materials in all the specified spatial zones of the problem. Options are available, however, to specify for each zone those materials for which photon production cross sections are desired and for each material to specify which reaction types are to be included in the calculation of the photon production cross sections. A problem arises for materials for which data are given for both total inelastic scattering (MT = 4) and for the individual levels and continuum (MT = 5 through 15, and 51 through 80). If the specific reaction types to be used by LAPH are explicitly given as input, there is no problem. However, under the flag MT = -1 (see discussion of input in Sec. III), which loosely means use all MT numbers for which photon production data are given in File 15, the code must make a decision concerning inelastic scattering. If photon production data are given in File 15 for MT = 4, it chooses to use these data only if data are not given for any MT in $\{5 \le MT \le 15 \text{ or } 51 \le MT \le 80\}$. Thus, when data are given for one or more of the individual levels and the user prefers to use the data in MT = 4, he must explicitly list the MT numbers desired. The flag MT = 0 means to ignore photon production from this material, and the material need not appear on the input ENDF/B data tape.

Given the set of reaction types, {MT}, for which photon production cross sections are desired, the total microscopic photon production cross-section matrix of material i is given by

$$\left[\sigma_{g,n}\right]_i = \left[\sum_{p\in\{MT\}} \sigma^p_{g,n}\right]_i \equiv \sum_{p\in\{MT\}} \left[\sigma_{g,n}\right]_{i,p} \qquad \text{(b-photons)}, \qquad (14)$$

where the subscript i, which has always been implicit in $\sigma^p_{g,n}$, is no longer suppressed. The energy production matrix $[\tilde{\sigma}_{g,n}]_i$ has an analogous definition. When either matrix is used below, the subscripts g and n will be suppressed unless desired for clarity.

In photon source calculations, the quantity usually of more interest than the microscopic photon production matrix, $[\sigma]_i$, is the macroscopic matrix given by

$$[\Sigma]_{i,j} = A_{i,j}[\sigma]_i \qquad \text{(photons/cm)}, \qquad (15)$$

where the scalar $A_{i,j}$ is the number density of the ith material in the jth region (units of b^{-1}-cm^{-1}). In all the following discussions, it is implicit that an exactly analogous development applies to the energy production matrix.

C. Spatially Dependent Photon Sources

To determine a spatially dependent photon source from the macroscopic photon production matrix, an appropriate flux vector must be known. Denoting this N-dimensional (column) vector by $[\phi(\vec{r})]_N$, where $\vec{r}$ symbolizes the spatial dependence, the photon source vector is given by

$$[\hat{S}(\vec{r})]_G = [\Sigma]_{GxN}[\phi(\vec{r})]_N \qquad (16)$$

$$\text{(photons/cm}^3\text{-sec)}.$$

In practice, the multigroup flux vectors $[\phi(\vec{r})]$ are calculated at discrete mesh intervals, Δr_m, and usually in one dimension (e.g., by the DTF-IV code[7]). Also, the fluxes are usually calculated for an arbitrarily normalized neutron source term, so the eigenfunctions generally require a renormalization factor, C, to account for the actual reactor power. The source is then given by

$$[S]_{i,m,p} = C[\Sigma]_{i,m,p}[\phi]_m , \qquad (17)$$

where j is implicitly determined by m. For most applications, the source vector of interest for a photon transport calculation is

$$[S]_m = C\left[\sum_i \sum_p \Sigma_{i,m,p}\right]\left[\phi\right]_m \qquad (18)$$

$$\text{(photons/cm}^3\text{-sec)},$$

and its energy production analog $[\tilde{S}]_m$ (eV/cm^3-sec). These source terms are listed under some output options by photon group at each mesh interval. Also, as an option, they may be output in formats suitable for the DTF-IV (photon transport) code.

III. INPUT INSTRUCTIONS

A. Background

Input to LAPH is generally in the DTF-IV format system, with the exception of the title and parameter cards at the beginning of the data. The DTF-IV system consists of a basic 12-column field, but the first three columns are reserved for a control flag, and the remaining nine columns are a data field. There are seven possible controls in the first column of the three-column subfield as follows:

0 or blank = normal input; the nine columns for data are read in normal FORTRAN E, F, or I format.

1 = repeat; the number in the data field is repeated the number of times specified by the integer NN in the second and third columns of the control field.

2 = interpolate; the number of interpolates, NN, specified in the second and third columns of the control field are placed between the number in the data field and the number in the succeeding data field.

3 = terminate; ends the data block--each data block must have this flag at the end.

4 = fill remainder of data block with the number in the data field.

5 = repeat the number in the data field 10*NN times.

9 = skip to next card.

Whether the data in the data field is integer or real is indicated by the first letter of the block name in the usual FORTRAN tradition.

A problem regarding terminology arises for LAPH when using DTF-IV input along with ENDF/B input, because the term material has a different meaning in each case. No completely satisfactory resolution was found, but by sacrificing purity for consistency, the term material in DTF-IV has been replaced by the term nuclide, which is consistent with the usage in MC[2], another code which is linked to LAPH. Also departing from DTF usage, "nuclide" does not include a mixture of nuclides. In LAPH, the term material is used strictly in the sense of a MAT in the ENDF/B system.

Units for input should be as follows:

Energy:	eV
Number density:	atoms/b-cm
Flux:	n/cm^2-sec
Length:	cm

The code has many error triggers which will lead to a call to the subroutine ERROR. The type of error encountered will be identified on the output listing by an error number. A brief description of this error can then be found in the comment card in ERROR for the corresponding error number (cf. listing in Appendix B).

B. Input Data Format

Data blocks are given in Table I in order of input, preceded by the corresponding variable name in LAPH. For the parameter table, the location (order) of the parameter is given first.

C. Array Size Restrictions

To keep the code operable on computers with small-size memories, restrictions must be placed on array sizes. The restrictions are presently as follows:

$$\begin{aligned} NFG &\leq 99 \\ NBG &\leq 99 \\ NGG &\leq 49 \\ IZM &\leq 10 \\ IM &\leq 100 \\ MS &\leq 50 \end{aligned}$$

D. Computer Requirements and Running Times

The LAPH code is presently operational on a CDC 6600 which has $65k_{10}$ memory and uses the full core. It requires no special hardware or software but does use a disk and one magnetic tape, viz., Tape 20 which is the ENDF/B data tape in Mode 3 (BCD card-image format in standard arrangement). The central processor time required for a problem with three regions, six materials, 10 mesh points, 26 neutron groups, and 11 photon groups, including calculation of both photon production matrices and photon source vectors (cf. the sample problem, Sec. III.E) was 3.5 min. All coding is in FORTRAN IV and should be compatible with FORTRAN compilers on other computers.

E. Sample Problem Input and Output

A sample problem for an infinite-slab physically unreal shield configuration is included for illustrative purposes. (The problem choice is restricted by the available ENDF/B data.) The shield

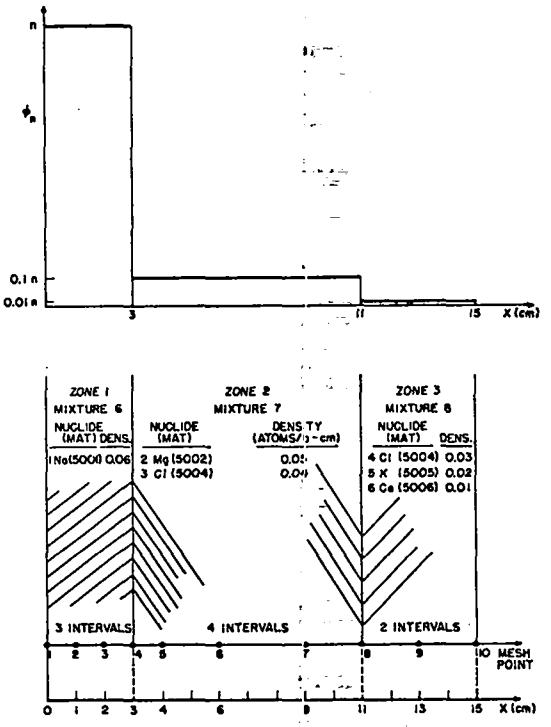

Fig. 2. Sample problem diagram.

configuration and composition are given in Fig. 2, and the corresponding input data are shown in Table II. Photon production from selected reactions was chosen as follows:

	Nuclide	MAT No.	MT Nos.
1	Na	5001	110
2	Mg	5002	102
3	Cl	5004	5→14 and 51→53
4	Cl	5004	0 (no reactions)
5	K	5005	-1 (all reactions)
6	Ca	5006	15

In the input for EG(10), there is a deliberate error giving the average gamma energy in the tenth group as 0.07 MeV instead of 0.7 MeV. In this case, the code will replace the value with the group median energy and proceed. This error is flagged in the sample output shown in Table III. Headings for the data blocks on the output listing are self-explanatory. A listing of the complete data deck for the sample problem is shown in Table II.

TABLE I

INPUT DATA FORMAT

A. Title Card (I6,11A6): Any integer for problem identification, and any BCD information for identification of output.

B. Integer Parameters (12I6):

Location	Name	Definition
1	NGG	Number of gamma groups.
2	NFG	Number of neutron fine groups.
3	NBG	Number of neutron broad groups.
4	IZM	Number of zones.
5	IM	Number of intervals.
6	MS	Number of mixture specifications (= length of mix tables).
7	MCR	Number of nuclides for which distinct fine-group cross sections and weighting functions are input.
8	MM	Number of reaction types, MT (= length of MT table).
9	NPM	Total number of nuclides plus mixtures.
10	IRES	Special resonance weighting option to be used? (0/1 = no/yes; 0 = Track A, 1 = Track B.)
11	IWØ	= 0, photon effective average energy for each group is input (Track 1).
		= 1, photon energy weighting function is yield function (Track 2).
12	IØØ	= 0, print $[\sigma_{g,n}]_{i,j}$ for each material i and zone j, and $\sum_i A_{i,j}[\sigma_{g,n}]_{i,j}$, the macroscopic matrices for each zone j.
		= 1, print all of Option 0 plus the source vector, $C \sum_i A_{i,j}[\sigma_{g,n}]_{i,j}\,[\phi]_m$, at each spatial point m. Note that m determines j.
		= 2, print all of Option 1 and punch the DTF-IV input source cards (cf. discussion of DTF-IV option).
		= 3, print only the matrix $\sum_i A_{i,j}[\sigma_{g,n}]_{i,j}$ for each zone j, along with the source vector $C \sum_i A_{i,j}[\sigma_{g,n}]_{i,j}\,[\phi]_m$.
		= 4, print all of Option 3 and punch the DTF input source cards.
		= 10, same as IØØ = 0, substituting the energy production matrices $[\tilde{\sigma}_{g,n}]_{i,j}$, etc.
		= 11, " " = 1, " " " "
		= 12, " " = 2, " " " "
		= 13, " " = 3, " " " "
		= 14, " " = 4, " " " "
		= 20, do both Options 0 and 10 (i.e., print both photon production and photon energy production matrices).
		= 21, do both Options 1 and 11.
		= 22, " " " 2 and 12.
		= 23, " " " 3 and 13.
		= 24, " " " 4 and 14.

[Note: The 2X series of output options requires an insignificant addition to the central processor time compared to the X or 1X series.]

TABLE I (continued)

C. Data Blocks (DTF-IV system): Dimension of variable is given if it is predetermined.

Name and Dimension	Definition
C(1)	Renormalization constant for $[\phi]$.
NMAT(IZM)	Number of materials in each zone for which photon production cross sections are desired.
NNM(2*MCR)	Nuclide sequence numbers (for mix table) and corresponding material (MAT) numbers, in successive pairs.
MZT(MCR)	For each MAT number in the NNM block, MZT is the number of values of MT to be entered in the next (MTN) block.
MTN(MM)	MT numbers for each MAT number given in the NNM block. MT = -1 means use all MT numbers for which photon production data exist in File 15, except possibly MT = 4 (cf. Sec. II.B). MT = 0 means calculate no photon production for this material.

If, and only if, IWØ = 0, the following data block appears:

EG(NGG)	Effective average energy, $\overline{E}_g$, for each gamma group. [Same for all materials and reaction types. Code checks that $E_g \leq \overline{E}_g \leq E_{g+1}$.]
EMG(NGG+1)	Gamma group energy mesh, in decreasing magnitude of energy.

The following eight data blocks will normally be punched by MC^2.

EMNF(NFG+1)	Neutron fine-group energy mesh, in decreasing magnitude of energy.
EMNB(NBG+1)	Neutron broad-group energy mesh, in decreasing magnitude of energy.

One set of the following six data blocks for each zone. Each block is preceded by a title card in 12A6 format.

LOOP ON ZONES [IZM]

LOOP ON MAT's [NMAT(IZM)]

RXSC(NFG)[ab]	Fine-group resonance capture cross sections, $\overline{\sigma}_\ell^{102,r}$, starting at top group. First card is a title card in 12A6 format.
RXSF(NFG)[ab]	Fine-group resonance fission cross sections, $\overline{\sigma}_\ell^{18,r}$, starting at top group. First card is a title card in 12A6 format.
SXSC(NFG)[b]	Fine-group smooth (including unresolved resonance) capture cross sections, $\overline{\sigma}_\ell^{102,s}$, starting at top group. First card is a title card in 12A6 format.
SXSF(NFG)[b]	Fine-group smooth (including unresolved resonance) fission cross sections, $\overline{\sigma}_\ell^{18,s}$, starting at top group. First card is a title card in 12A6 format.
RW(NFG)[ab]	Fine-group resonance weighting functions for the zone, starting at top group. First card is a title card in 12A6 format.
SW(NFG)	Fine-group smooth (flux) weighting functions for the zone, starting at top group. First card is a title card in 12A6 format.

The following six data blocks are identical to their homologous blocks in DTF-IV. In fact, for many LAPH problems, they will be identical to those for the DTF-IV problem used to compute the neutron flux vectors.

R(IM+1)	Radii of the spatial mesh points.
MA(IM)	Zone numbers for each interval.
MZ(IZM)	Mixture number in each zone.
MB(MS)	Mixture numbers for mix table.
MC(MS)	Mix command: Specification of nuclides in the mixtures.
XMD(MS)	Mix density of the nuclide in the mixtures.

Lastly, the data block for the neutron flux vectors appears in a format exactly like that used for DTF-IV flux dumps, i.e.,

PHI(IM,NBG)	Normalized neutron fluxes by columns (i.e., by mesh interval and then by neutron broad groups).

[a] These should be entered even for nonresonance materials. In such case, any numbers may be used to fill the fields, but MC^2 will automatically output zeros in this block.

[b] Delete this data block if IRES = 0.

ACKNOWLEDGMENTS

The authors are indebted to Morris E. Battat and Raphael J. LaBauve for their contributions to the conceptual design of the LAPH code, as well as for their counsel on the theory and programming. Also, we gratefully acknowledge the kind permission of Kaye D. Lathrop and Forrest E. Brinkley to use subroutines from the DTF-IV code.

APPENDIX A

COMMENTS CONCERNING CODE OPERATION AND SUBROUTINES

As shown in Fig. A.1, the LAPH code has been divided into three main parts, each of which is a primary overlay. The main overlay, OVERLAY (0,0), is very short and serves principally to define unlabelled COMMON and labelled COMMON/TAPES/ and to call the three primary overlays, namely, OVERLAY (1,0), (2,0), and (3,0). In OVERLAY (1,0), the input is read in DTF-IV format and binary Tape 5 is prepared for use as input to OVERLAY's (2,0) and (3,0); in OVERLAY (2,0), the photon production and energy production matrices for each material in each zone are calculated and written onto binary Tape 18; in OVERLAY (3,0), the matrices on Tape 18 are combined appropriately, and the photon source and energy source vectors are calculated.

A brief description of each of the subroutines follows.

OVERLAY (0,0)

PROGRAM MAIN serves to define unlabelled COMMON and labelled COMMON/TAPES/ and to call the three primary overlays.

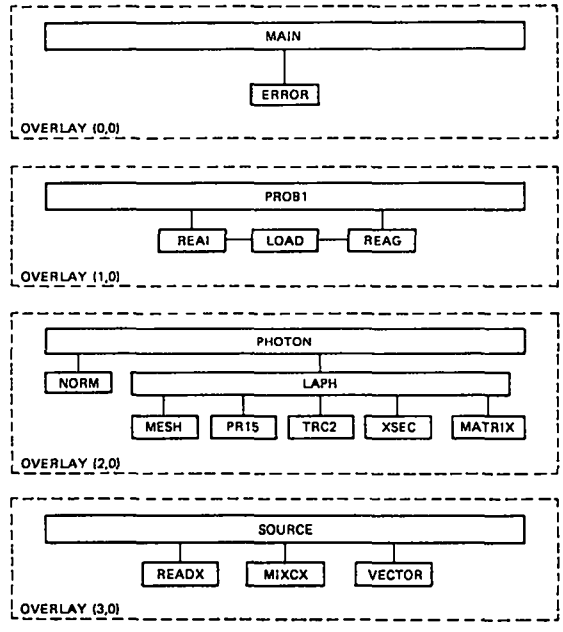

Fig. A.1. Arrangement of overlays and subroutines.

SUBROUTINE ERROR is called if there is an error in the input data or if any core storage allotments have been exceeded. An error stop number is printed, and execution is terminated. A complete catalog of the possible fatal error returns is included as a part of this subroutine. Other error messages are printed by the various subroutines when the error is nonfatal.

OVERLAY (1,0)

PROGRAM PROB1 reads all of the input data for the problem, does preliminary checking thereon, and arranges the data on binary Tape 5 in a form convenient for use in OVERLAY's (2,0) and (3,0).

SUBROUTINE REAI and SUBROUTINE REAG are DTF-IV routines. They are called by PROB1 to read integer and floating-point data, respectively, when these data are given in the DTF-IV format.

SUBROUTINE LOAD is another DTF-IV routine and is called by the two subroutines mentioned above. This routine interprets the DTF-IV control flags and fills out the integer and floating-point arrays accordingly.

OVERLAY (2,0)

PROGRAM PHOTON reads the input data from Tape 5 and supervises the calculations for each zone and each material within each zone.

SUBROUTINE INTG computes the integral of y(x) between two points x_1 and x_2, where values of y(x) are given at x_3 and x_4 such that $x_3 \leq x_1 < x_2 \leq x_4$. The dependence of y(x) on x between the two tabulated points (e.g., linear-linear or log-log) must be specified.

FUNCTION LOCT locates the mesh interval in which a given variable lies.

SUBROUTINE TERP1 interpolates between two specified points of y(x) vs x, assuming a dependence (e.g., linear-linear or log-log) which must be specified.

SUBROUTINE LAPH supervises the calculation of the photon production and energy production matrices for each material.

SUBROUTINE NORM normalizes the fine-group weighting functions over each broad group.

SUBROUTINE RSF3 reads tabulated arrays from the ENDF/B data tape.

SUBROUTINE MESH forms the energy mesh to be used in the numerical integration over neutron energy. The fine-group energy mesh is augmented with the energies at which the neutron cross sections are tabulated in File 3. Only those cross-section tables corresponding to reaction types specified in the input data are considered. This routine interprets the "MT = -1" command in the input specification and determines which MT numbers are to be used.

SUBROUTINE PR15 reads the photon production data from File 15 of the ENDF/B tape. For a continuous energy distribution under Option 1, the photon group yields, $Y_g(E)$ and $\tilde{Y}_g(E)$, are calculated on either Track 1 or 2 and written onto Tape 15. For distributions under Option 1 at discrete gamma energies, the yields are written directly onto Tape 17. The appropriate transition and conditional probabilities under Option 2 are read from the ENDF/B tape and are written onto Tape 16 for later use in SUBROUTINE TRC2.

SUBROUTINE TRC2 reconstructs the microscopic photon production cross sections from the transition arrays (read from Tape 16) and the appropriate cross sections (read from the ENDF/B tape File 3), integrates over the neutron fine groups, and writes the results on Tape 16.

SUBROUTINE MATRIX reads the microscopic fine-group photon and energy production matrix elements (τ's and ρ's) from Tape 16. It then performs the sum over fine groups which results in the photon production and energy production matrices for each reaction type. Finally, the sum over reaction types is taken to produce the G x N matrices which are written onto Tape 18.

OVERLAY (3,0)

PROGRAM SOURCE supervises the calculation of the photon source and energy source vectors.

SUBROUTINE READX reads either the photon production or the energy production microscopic matrices from Tape 18.

SUBROUTINE MIXCX multiplies the microscopic matrices by the specified number densities and prints the macroscopic matrices.

SUBROUTINE VECTOR multiplies the macroscopic matrices by the appropriate flux vectors and the scalar renormalization constant to give the source vectors.

SUBROUTINE PUNCR punches both integer and floating-point arrays in DTF-IV format.

APPENDIX B

INDEX'ed (CROSS REFERENCE) LISTING OF LAPH
