Abstract

Sensitivity profiles of the multiplication factor and several central reaction rate ratios for five CSEWG fast reactor benchmarks, ZPR-6/7, ZPR-6/6A, ZPR-3/11, ZPR-3/56B, and GODIVA, are presented in graphic form and in tabular form using SENPRØ format. A summary table of total relative sensitivities for each of these five benchmarks is also given.

Introduction

The ORNL sensitivity analysis code system FORSS^{1,2} is a tool for studying relationships between cross sections, integral experiments, performance parameter predictions, and associated uncertainties. Fundamental to all studies involving sensitivity analysis are the relative sensitivities or sensitivity coefficients, which are the derivatives of the logarithms of the performance parameters with respect to the logarithms of the nuclear data parameters. Especially important are the sensitivity profiles, which are the energy-dependent sensitivities. Accordingly, a substantial part of the FORSS system is devoted to the calculation of the sensitivity coefficients and profiles, while the remainder of the system is devoted to various applications which use these quantities.

Although these sensitivity coefficients and profiles are required for many applications, they may be considered as an end unto themselves, for a great deal of understanding and insight is obtained by studying and comparing these sensitivities. It is with this thought in mind that the tables and plots are herewith reported. In addition, for those interested in applying the coefficients, the SENPRØ format³ for reporting sensitivity coefficients is presented in Appendix A, and the sensitivity data are tabulated in Appendix B using SENPRØ.

The Scope of the Report

The sensitivities reported here are based on the analysis of five CSEWG fast benchmarks,⁴ ZPR-6/7, ZPR-6/6A, ZPR-3/56B, ZPR-3/11, and the GODIVA assembly. These assemblies were chosen because they are well documented and represent a range of reactor types which are of interest.

ZPR-6/7 is a large (3100 liters) plutonium-oxide fueled fast critical assembly with a soft spectrum and other characteristics representative of several LMFBR designs. The core is blanketed with depleted uranium.

ZPR-6/6A is similar except that the fuel is enriched uranium rather than plutonium. ZPR-3/11, with its enriched uranium metal and ^{238}U blanket, provides additional opportunity to test ^{235}U and ^{238}U cross-section sensitivities at the higher fertile-to-fissile ratio of 7:1. ZPR-3/56B is a plutonium-oxide fueled critical assembly with a relatively large core and a nickel reflector. GODIVA is an enriched-uranium metal sphere.

Three types of response were considered: (1) the multiplication factor k , (2) a central capture-to-fission ratio, or (3) a central fission-to-fission ratio. (A central ratio is one for which the reactions considered are at the central point of the core.) The nuclear data included fission neutron yields and neutron reaction cross sections for fission, capture, elastic scattering, total inelastic scattering, and inelastic scattering from individual levels as well as from the continuum.

A positive flux solution to the homogeneous reactor transport equations exists only if a steady-state condition relating the parameters is satisfied.⁵ If initially this steady-state condition is satisfied, then an arbitrary variation in one parameter will in general cause the condition to become violated. Hence, a new positive solution can be found only if another parameter is simultaneously varied in such a way as to reestablish the validity of the steady-state condition. All results reported here are based on the usual computational convention of introducing the multiplication factor k , thereby transforming the steady-state condition into the definition of k . It is k which has been varied in response to the variation of the parameters. It is important to recognize this fact in understanding and applying the sensitivity coefficients. For this is not in accord with engineering design conventions which typically vary the enrichment, or with operating conventions in which a control rod position is changed in order to maintain the steady-state condition.

The sensitivities presented represent what are presently available at ORNL and are in no sense complete. There are omissions in assemblies,

performance parameters, reaction types, and nuclides. However, it is felt that many of the most important coefficients are represented, and that these, being already quite numerous, were of sufficient interest to present in one report. These sensitivity coefficients have been compiled into a library for distribution in a computer-readable format. The data are available on tape from the Radiation Shielding Information Center at Oak Ridge National Laboratory. This library is continually growing and will be documented at appropriate intervals in the sense of the "open code package."⁶

The Method

The method of calculating the sensitivity coefficients has been extensively described in previous reports and only a brief description is included here for completeness.

The first order of business of almost any calculation is the formation or selection of a multigroup cross-section library. The cross-section library upon which these calculations were based was ORNL's 126/36 pseudo-composition independent fine-group LMFBR neutron-gamma coupled library.^{7,8} This library in turn was based on ENDF/B-IV data. The energy bounds for the 126 neutron groups are listed in Table 1. For each region in each reactor assembly, self shielding was employed to obtain a library of 126 neutron energy group composition-dependent cross sections. Legendre scattering components were included for values of ℓ from 0 through 3.

The ANISN discrete-ordinates transport code⁹ (in S_4 , P_3 approximation) was applied to one-dimensional models of the assemblies for the calculation of forward and adjoint fluxes, as well as the multiplication eigenvalue. These in turn were used in the JULIET code for calculating the values of the performance parameters and the corresponding sources to the generalized-adjoint transport equations. The generalized adjoint solutions of these latter equations were provided by ANISN (modified to allow negative fluxes) and then used in the SWANLAKE

code¹⁰ for the calculation of the sensitivity coefficients. More detail concerning the functional relationships between these codes when employed for sensitivity analysis is provided in ref. 2.

The Results

The results of the sensitivity calculations described briefly above are presented here in the form of summary tables and graphs. Agreement with previously reported¹¹ results using independent methods is good. The graphs (Figs. 1-219) present relative sensitivities per unit lethargy^a as a function of the neutron reaction energy. We have chosen to plot the profiles in this form because the relative sensitivity per unit lethargy is independent of the group structure if the group structure is sufficiently fine. Thus these plots can be compared directly with similar plots which use a different group structure. Observe that these are log-log plots in which a solid continuous curve represents a negative quantity and a broken-line dashed curve represents a positive quantity.

Tables 2-6 present for each response, nuclide, and reaction, the total relative sensitivity, which is the relative sensitivity of the response with respect to the group reaction cross section summed over all groups. Such a total relative sensitivity is actually a relative sensitivity with respect to a group-independent scale factor λ . This multiplicative factor affects the associated cross section or yield (considered as mathematical variables) in the same proportion at all energies and in all groups. Thus, if the scale factor λ increases by 10%, all the group cross sections for the associated reaction type increase by the same 10%. For convenience λ may be set to unity when

^aNote the definitions used here: The sensitivity of response R with respect to a nuclear data parameter such as the group i cross section σ_i is the derivative $dR/d\sigma_i$. The sensitivity coefficient or relative sensitivity of response R with respect to the group cross section σ_i is $(dR/R)/(d\sigma_i/\sigma_i)$. The relative sensitivity per unit lethargy of R with respect to an energy (or rather a group) dependent parameter such as σ_i is $[(dR/R)/(d\sigma_i/\sigma_i)]/\Delta u_i$ where Δu_i is the lethargy width of group i.

the group cross sections have their nominal values σ_i^0 . Then the group cross sections are given by

$$\sigma_i = \lambda \sigma_i^0 . \quad (1)$$

In contrast to the plots, the sensitivities given in Appendix B using the SENPRØ format are not per unit lethargy but are simply relative sensitivities to the group cross sections or group yields. The reason for this is that these are the quantities currently used in numerical computations.

Discussion

A study of the sensitivity profiles leads to many interesting insights. In general, the collection of profiles show that a great amount of structure is possible in the energy dependence of the sensitivity coefficients. Frequently, such structure can be traced back to cross section resonances, thresholds, etc. In addition, comparison of related profiles is often enlightening. However, detailed discussion of this is beyond the purpose of the present report.

The remainder of this discussion is devoted to a few items which are pertinent to interpreting the summary tables of total relative sensitivities. For interpreting the summary tables it is useful to first calculate the direct effect contribution to the total relative sensitivity. This contribution is that which arises from the explicit dependence of the performance parameter on the nuclear data parameter of interest, which, as discussed in the previous section for a total relative sensitivity, is a scale factor. In calculating the direct effect contribution, the shape of the forward flux (as well as that of the adjoint flux) is assumed to remain unchanged.

The following theorem is especially applicable to the calculation of direct effects to total sensitivities of reaction rate ratios: If

the mathematical expression for a response is explicitly homogeneous of degree n in a nuclear data parameter, then the direct effect contribution to the relative sensitivity of that response with respect to the nuclear data parameter is n . Reaction rate ratios are typically homogeneous of degree +1, -1, or 0 in the scale factors (not the group cross sections). Accordingly, the direct effect contribution to the total sensitivity of a reaction rate ratio is typically +1, -1, or 0.

For example, the ^{238}U -capture-to- ^{235}U -fission ratio is homogeneous for degree 1 in the ^{238}U -capture scale factor, of degree -1 in the ^{235}U -fission scale factor, and of degree 0 in the ^{235}U -capture scale factor. The corresponding direct effect contributions to the total relative sensitivities are 1, -1, and 0 respectively.

The direct effect gives the contributions to the sensitivity coefficients ignoring explicit variations in the forward (and adjoint) flux. Frequently, however, it is just those effects due to flux modifications, the indirect effects, which are most interesting. These indirect effects arise largely through the shielding of one reaction by another (or itself) and include self shielding as well as the shadowing of one resonance by another. There are also resulting modifications to the leakage and to the slowing down.

A measure of these indirect effects is given by the difference between the total relative sensitivity and the direct effect contribution. Deviations from the direct effect contribution range typically from very small values through ten to twenty percent. Especially large is the effect of inelastic scattering from ^{238}U on the ^{238}U -fission-to- ^{235}U (or ^{239}Pu)-fission ratio. In ZPR-3/11 (for which the fertile-to-fission ratio is greater than seven) this gives the largest deviation from the direct effect (-0.654 compared to 0.0).

For those total relative sensitivities of reaction rate ratios with a direct effect contribution of unit magnitude the indirect effect

contribution is frequently of opposite sign to the direct effect contribution, resulting in total relative sensitivities with magnitudes less than unity. These illustrate that a reaction cross section commonly shields itself more than it shields another reaction cross section. For example, in ZPR-6/6A the total relative sensitivity of $^{28}\text{f}/^{25}\text{f}$ with respect to ^{235}U fission is -0.63 compared to -1.0, the direct effect contribution. This is an extreme example in that the indirect contribution is quite large.

On the other hand, there are several examples for which the magnitude of the total relative sensitivity is greater than the unit contribution given by the direct effect. These illustrate shielding (or another cross section) which is greater in effect than the self shielding. Thus, in ZPR-3/56B the total relative sensitivity of the central reaction rate ratio $^{49}\text{f}/^{25}\text{f}$ with respect to ^{239}Pu fission is 1.0726, which is 7% greater than the direct contribution. This shows that an increase in the ^{239}Pu fission scale factor (and, hence an equal increase in all the group cross sections for ^{239}Pu fission) results in a flux spectrum modification at the center of the core of ZPR-3/56B which modification decreases the ^{235}U fissions more than it decreases the ^{239}Pu fissions. In other words, the ^{239}Pu fission reaction shields the ^{235}U fission reaction more than itself at the center of the ZPR-3/56B core. Similarly, ^{235}U fission in ZPR-6/6A and in ZPR-3/11 and ^{239}Pu fission in ZPR-6/7 all shield ^{238}U capture more than themselves to produce total relative sensitivities with magnitudes greater than unity. (The word "shielding" in the above discussion is meant to include energy-transfer effects. This is a somewhat broader use of the word, which ordinarily refers to spatial effects due to absorption.)

The above discussion and results apply to sensitivity coefficients for reaction rate ratios, which are generally homogeneous in the nuclear data scale factors. Generally, they do not apply to sensitivity coefficients for the multiplication factor k because the mathematical expression for k is generally not homogeneous in any scale parameter.

For this and other reasons, it is not convenient to divide k-sensitivities into direct-effect of the indirect-effect contributions. The sensitivity coefficient for k with respect to nuclear data parameter a naturally breaks up into two terms - one from the source and the other from the losses. The expressions for these are given by

$$\frac{a}{k} \frac{dk}{da} = f_a - k \alpha_a \quad (2)$$

where f_a is the fraction of adjoint-weighted fission sources which are of degree 1 in the parameter a and α_a is the ratio of loss terms of degree 1 in the parameter a to the total adjoint-weighted fission source. The mathematical expression for these are

$$f_a \equiv \frac{(\phi^*, B_a \phi)}{(\phi^*, B \phi)} \quad (3)$$

$$\alpha_a \equiv \frac{(\phi^*, A_a \phi)}{(\phi^*, B \phi)} \quad (4)$$

where B_a is the part of the fission source proportional to parameter a, and A_a is the loss operator (everything but fission) proportional to parameter a, and ϕ and ϕ^* are the forward and adjoint fluxes respectively.

Equation (2) immediately shows that the sum of all the sensitivity coefficients with respect to the neutron fission yields its unity. Another relation which is obvious from Eq. (2) is that the capture sensitivities are simply given by -k times the adjoint-weighted nuclide capture to total fission ratio. Only slightly less obvious is that the difference between the yield sensitivity and the corresponding fission reaction sensitivity is simply k times the nuclide capture sensitivity divided by the nuclide capture-to-fission ratio (adjoint weighted).

The unity sum rule given above for sensitivity coefficients of k with respect to neutron yield \bar{v} should be compared with the zero sum rule for sensitivity coefficients of other performance parameters which do not depend explicitly on the multiplication factor or a neutron yield. Such

sensitivity coefficients add algebraically to zero when summed over all neutron yields because the resulting change in k (assuming k is not reset) exactly compensates the changes in the neutron yields.

Conclusions

The sensitivity coefficients are an important data base for calculation of many quantities of interest in reactor design. In addition, a study of sensitivity profiles and of the total relative sensitivities leads one to many important insights into reactor physics. The sensitivity profiles and the summary tables contained in this report and the data file in SENPRØ format in the Appendix are presented as aids to attaining the above ends.

Acknowledgements

The authors wish to thank J. D. Drischler for his aid in organizing the profiles, handling the data, and especially for creating the file of sensitivity coefficients in SENPRØ format. Thanks are due to E. M. Oblow for his helpful discussions concerning the eternal problem of understanding and interpreting what the profiles mean. We owe our gratitude to Virginia Glidewell for typing this report and organizing it in its final form.

APPENDIX C
An Example of Using the Graphs
and the SENPRO Data

Consider the following problem: what is the percent change in the ZPR-6/6A reaction-rate ratio (^{238}U capture)/(^{235}U fission) due to a 10% uniform increase in the ^{235}U fission cross section in the energy range 0.1 to 0.2 MeV.

- a) An estimate from the graph at the top of page 71 gives a value for the relative sensitivity per unit lethargy of -0.19 (solid lines represent negative values) for the range 0.1 to 0.2 MeV. The percent change in the response is given by

$$(-0.19) [\ln(0.2/0.1)] 10\%$$

which gives a decrease in the response of 1.3%.

- b) Table 1 on page 4 shows that 0.2 MeV lies in group 62 and 0.1 lies in group 74. We then sum the sensitivity coefficients at the top of page 170 over groups 63 through 73 adding 0.7594 of the group 62 and 0.8414 of the group 74 sensitivities (interpolating linearly in lethargy). This gives a total relative sensitivity of -0.1325, which, when multiplied by 10%, gives a predicted decrease of 1.325% in the response .

Utility programs for computer calculations using such sensitivity data in SENPRO format are available on request from Oak Ridge National Laboratory through Radiation Shielding Information Center.
