

$^{99}\text{Tc}(n,\gamma)$ E=thermal 2004Fu30,1979Pi08

Type	Author	History	Citation	Literature Cutoff Date
Full Evaluation	Balraj Singh and Jun Chen		NDS 172, 1 (2021)	31-Jan-2021

2004Fu30: thermal neutrons were produced from the Los Alamos Omega West Reactor. Target was 84.6 mg 100% pure Tc metal. γ rays were detected with a 30-cm³ coaxial intrinsic Ge detector inside a 20-cm-diam by 30-cm-long NaI(Tl) annulus. Measured $E\gamma$, $I\gamma$ in absolute units, cross sections. Deduced levels. A total of 1086 γ rays from 30.8 to 6593.2 keV are reported with intensities given in terms of absolute cross sections. **2005FuZY** is by the same group.

1979Pi08 (also **1978HeZQ**): thermal neutrons were produced from the High Flux Reactor of the Institute Laue-Langevin in Grenoble. Target was metallic Tc power. γ rays were detected with Ge detectors and a bent-crystal spectrometer consisting of a 32-cm³ Ge(Li) detector surrounded by a 50-cm-diam by 40-cm-long plastic scintillator and a 10.2-cm-diam by 15.2-cm-long NaI(Tl) detector; conversion electrons were detected with the β -spectrometer BILL. Measured $E\gamma$, $I\gamma$, $E(\text{ce})$, $I(\text{ce})$, $\gamma\gamma$ -coin, $\gamma\gamma(t)$. Deduced levels, J , π , $T_{1/2}$, conversion coefficients, γ -ray multipolarities. Complete γ -ray data are given in **1978HeZQ**. Bent-crystal spectrometer used for γ rays below 800 keV and germanium detector for the higher energy region. Full details of γ -ray intensity data (per 100 neutron captures) and $E\gamma$ data above 596 keV from **1978HeZQ** are listed under 'document' records in the ENSDF file, as are $E\gamma$ data from **2004Fu30** below 596 keV.

There is general agreement of $E\gamma$ and $I\gamma$ data between the two studies: **2004Fu30** and **1979Pi08** (also **1978HeZQ**). The differences are noted either in the comments or in 'document' records in the ENSDF.

Others:

2014Ki08: measured $E\gamma$, $I\gamma$ at JPARC/ANNRI facility in Japan. This paper is a conference report and not followed by a regular paper. Primary γ rays of 5715 and 6221 were reported. Primary γ rays were also reported from four resonances.

2008WeZX: measured $\gamma\gamma$ -coin. With gate at 299 keV γ ray, following γ rays were seen: 31, 43, 75, 99, 105, 179 and 181 keV. Authors suggested that the 299-keV γ may be a doublet, and that several modifications were needed in the level scheme proposed by **1979Pi08**, the authors did not compare their results with those in **2004Fu30**. **2008WeZX** is a conference paper, not followed by a journal publication.

2005BeZV, **2002Mo42**: E=cold neutrons. Measured prompt and delayed γ , deduced partial and total cross sections.

1995Ha46, **1972TaZM** (reported a total of 30 γ rays from 23 to 6563 keV).

[†] From the Adopted Levels.

[‡] From least-squares fit to E γ data. The uncertainties of secondary γ rays were doubled in the fitting procedure since the quoted relative uncertainties result in an overall poor fit to the decay scheme with normalized $\chi^2=110$ and 42 γ -ray energies deviating by 3 or more standard deviations from the fitted values. The current fitting gives somewhat higher normalized $\chi^2=6.5$ and about 15 E γ values deviating by 3 or more standard deviations from the fitted values. The uncertainties on level energies are relative. The absolute uncertainty, taking into account the calibration uncertainty of 0.05 keV, can be obtained by adding 0.04 keV in quadrature for each level.

[#] Level suggested by the evaluators on the basis of (p,n γ) results.

[@] Level proposed by 2004Fu30.

[&] s-wave neutron capture in ^{99}Tc (g.s. $J^\pi=9/2^+$). 2004Fu30 give 6765.20 4, 2017Wa10 mass evaluation gives 6764.4 10.

⁹⁹Tc(n,γ) E=thermal 2004Fu30,1979Pi08 (continued)

γ(¹⁰⁰Tc)

I_γ normalization: Intensities are given by 2004Fu30 in units of milli-barns, here these are given in terms of 0.1b.

[†] From bent-crystal spectrometer data of 1978HeZQ for γ data below 596 keV, unless otherwise stated. Above this energy values are mainly from 2004Fu30 from Compton suppressed Ge detector used in the suppression mode in the intermediate energy region and in the pair spectrometer mode for higher energy γ rays. Corresponding values for most γ rays are also available from 1978HeZQ. Quoted uncertainties in energies from bent-crystal data are from relative precision, defined by $\Delta E=(5 \times 10^{-8}) \times E_\gamma^2/n$, where n=order of the spectrum and the calibration uncertainty is 0.05 keV, the same as that for the 539.59γ and 590.83γ (calibration lines) from ¹⁰⁰Tc β⁻ to ¹⁰⁰Ru, which should be added into the uncertainty in quadrature.

[‡] From 2004Fu30, unless otherwise stated. Values given by 2004Fu30 are in units of milli-barns, the evaluators have converted these to units of 0.1b. When values are taken from 1978HeZQ, these are adjusted upwards by a factor of 3 for γ's below 400 keV and by a factor of 2 for γ's above 400 keV. The uncertainties for γ's from bent-crystal data are not given by 1978HeZQ, the evaluators have assigned 5% to γ's with $I_\gamma \geq 1.0$, 10% to γ's with $I_\gamma = 0.1$ to 1.0 and 25% to γ's with $I_\gamma < 0.1$.

From ce data of 1979Pi08. The γ-ray and ce intensities are known per 100 n-captures from 1979Pi08 and/or 1978HeZQ.

@ From 2004Fu30.

& Placement from 294.9 level (1979Pi08) replaced by the 94.251γ based on better energy agreement (evaluators).

$\gamma(^{100}\text{Tc})$ (continued)

- ^a Poor fit in the decay scheme, deviates by 0.01 to 0.02 keV, several times the quoted relative uncertainty.
- ^b Placement suggested by the evaluators on the basis of (p,n γ) results.
- ^c Probably a doublet populating both levels at 500.02 and 500.14 keV.
- ^d γ From 2004Fu30 only.
- ^e γ from 1978HeZQ only.
- ^f From 1978HeZQ.
- ^g Placement from 2004Fu30.
- ^h Placement from 1979Pi08.
- ⁱ From 2004Fu30.
- ^j Intensity taken from 1978HeZQ but adjusted by the evaluators to match the scale of 2004Fu30, the adjusted value is a factor of 2 or 3 larger depending on the γ -ray energy range.
- ^k Intensity per 100 neutron captures.
- ^l Total theoretical internal conversion coefficients, calculated using the BrIcc code (2008Ki07) with Frozen orbital approximation based on γ -ray energies, assigned multipolarities, and mixing ratios, unless otherwise specified.
- ^m Multiply placed with undivided intensity.
- ⁿ Placement of transition in the level scheme is uncertain.
- ^x γ ray not placed in level scheme.

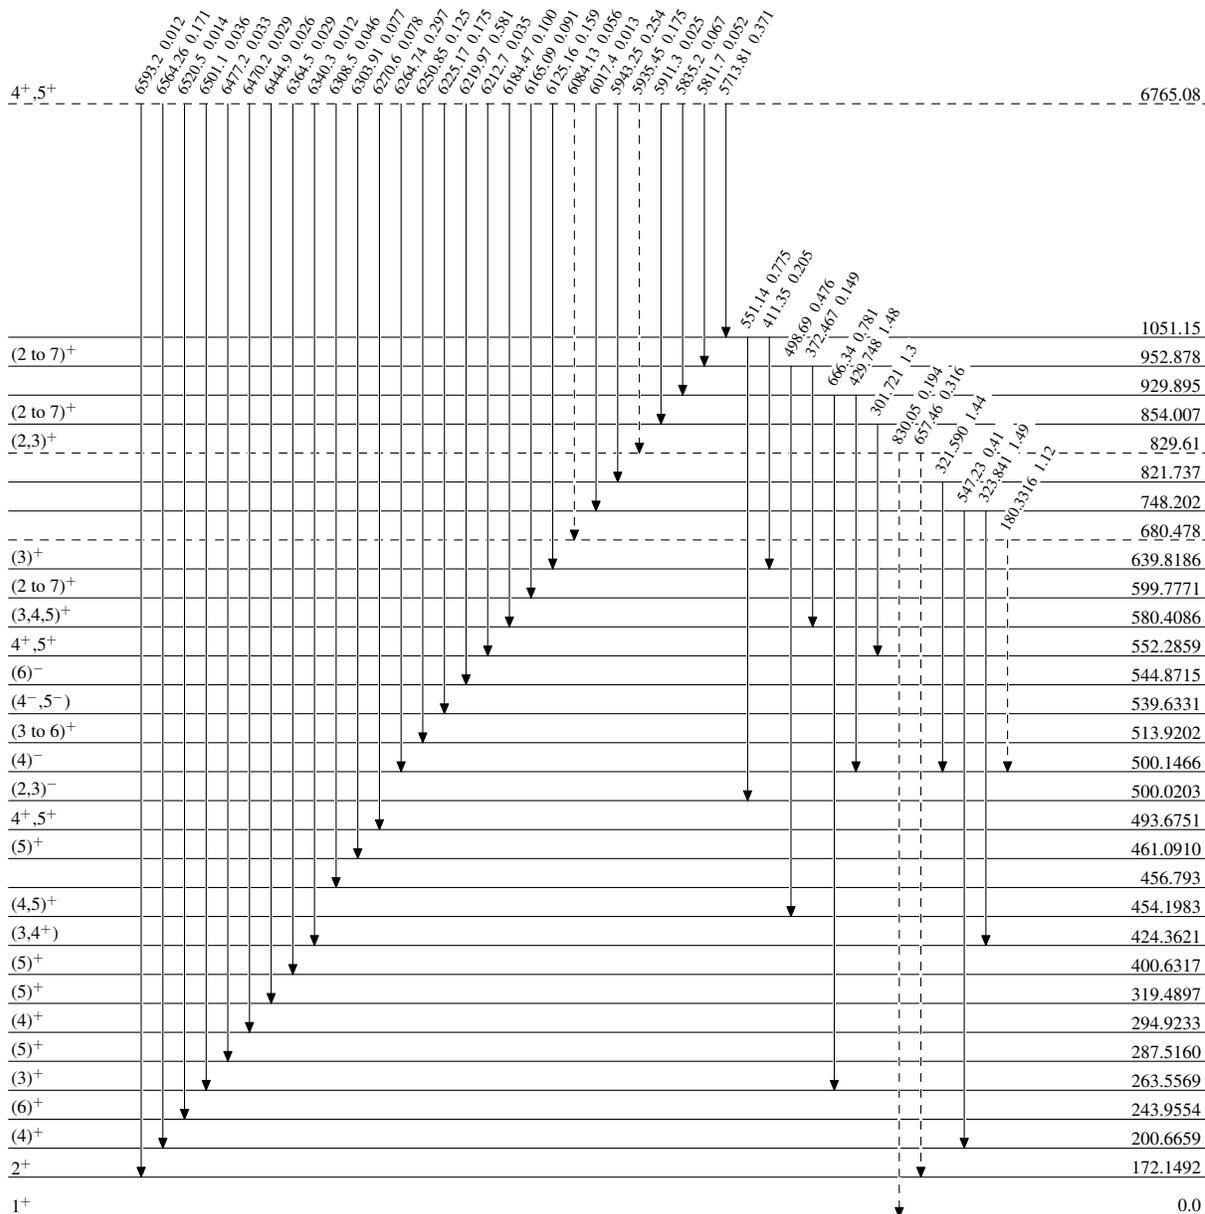

$^{99}\text{Tc}(n,\gamma)$ E=thermal 2004Fu30,1979Pi08

Legend

Level Scheme

Intensities: In units of 0.1b

- ▶ $I_\gamma < 2\% \times I_\gamma^{max}$
- ▶ $I_\gamma < 10\% \times I_\gamma^{max}$
- ▶ $I_\gamma > 10\% \times I_\gamma^{max}$
- - -▶ γ Decay (Uncertain)

$^{100}_{43}\text{Tc}_{57}$
