Target ^{110}Cd $J^\pi(\text{g.s.})=0^+$.

1975Ch07: E(d)=16 MeV beam was produced from the University of Pittsburgh three stage Van de Graaff accelerator. Target was a 95% isotopically pure self-supporting foil of $553 \mu\text{g}/\text{cm}^2$ thick. Tritons were momentum analyzed by an Enge split-pole spectrograph (FWHM=23 keV) and recorded in photographic emulsion plates. Deduced levels, J^π , L, spectroscopic factors from DWBA analysis.

[†] Values shown here are for the purpose of extracting corresponding spectroscopic factors.

[‡] Spectroscopic factor is deduced based on: $(d\sigma/d\Omega)(\text{exp})/(d\sigma/d\Omega)(\text{DWBA}) = 3.33 \times C^2S$. [1975Ch07](#) assign 15% maximum uncertainty in the absolute cross sections.
