

**<sup>157</sup>Yb ε decay 1994Xu07,1996Xu03,2008VaZV**

Type	Author	History Citation	Literature Cutoff Date
Full Evaluation	N. Nica	NDS 132, 1 (2016)	4-Dec-2015

Parent: <sup>157</sup>Yb: E=0.0; J<sup>π</sup>=7/2<sup>-</sup>; T<sub>1/2</sub>=38.6 s 10; Q(ε)=5311 28; %ε+%β<sup>+</sup> decay=99.5

The scheme is from 1994Xu07, who produced the <sup>157</sup>Yb by an <sup>16</sup>O beam on <sup>147</sup>Sm, with some added data from 1996Xu03 (same authors). γ placements are from γγ coincidence data.

With a Q value of 5300 keV, this decay scheme is clearly very incomplete since levels are only reported up to 834 keV.

I(ε+β<sup>+</sup>) values are given by 1994Xu07, but for two reasons they are not given here. First, the values of 1994Xu07 depend critically on assumptions concerning the γ-ray multiplicities. Second, the scheme is very incomplete since levels are only reported to 834 keV compared to a Q value of 5300 keV. Also, the strongest γ, at 23 keV, is not placed in this scheme.

The ratio of the intensities of the K x-rays and the 511 photons suggests a major share of the decays are to levels above 834 keV and even above 2000 keV. The largest single component of the K x ray intensity from internal conversion will come from the 69 γ and its maximum value will be ≈ 250 if it is an M1 transition. Therefore, the measured I(Kαx) = 1660 150, from which one can calculate that I(Kx) ≈ 2100, is primarily from ε decay. Since the I(511) = 821 13 should correspond to 2 times the β<sup>+</sup> decays (this assumes all of the β<sup>+</sup> were stopped near the source), the measured capture to positron ratio is ≈ 5. For comparison, the theoretical capture to positron ratios are: to 0 keV level 0.35, to 835 level 0.65, to a 2000 level 2.0, and to a 3000 level 10. Therefore, most of the ε+β<sup>+</sup> decays are to levels above 2000 keV, assuming that the I(Kαx) and I(511) are correct.

<sup>157</sup>Tm Levels

E(level) <sup>†</sup>	J <sup>π</sup> <sup>‡</sup> #	T <sub>1/2</sub>	Comments
0.0@	1/2 <sup>+</sup>		
35.23 11		1.6 s	According to 2008VaZV this level is not populated directly by <sup>157</sup> Yb ε decay (presumably because of nuclear structure arguments). J <sup>π</sup> : (7/2 <sup>-</sup> ) from (E2) γ from (3/2 <sup>-</sup> ) (2008VaZV). T <sub>1/2</sub> : Quoted by 2008VaZV from a 1999 report (with no given evidence this value looks questionable and it is not adopted); other value: > 40 ns from lack of observed coincidences in xγ(t) measurement (1996Xu03).

834.70 21			

<sup>†</sup> From least-squares fit to γ energies.

<sup>‡</sup> From Adopted Levels, Gammas dataset.

# In comments: from 1994Xu07 and 1996Xu03 and based on the suggestion that these levels form bands. Same J values are retrieved by 2008VaZV (mentioned as deduced from γ-ray multiplicities from measured ICC; however no evidence is shown) while parities are only partially in agreement with 1994Xu07 and 1996Xu03 (which makes their band assignments more

<sup>157</sup>Yb ε decay [1994Xu07](#),[1996Xu03](#),[2008VaZV](#) (continued)

<sup>157</sup>Tm Levels (continued)

hypothetical). As there is not enough evidence, neither the  $J^\pi$  values nor the band assignments have been adopted.

@ Band(A): Possibly  $K^\pi=1/2^+$  band.

& Band(B): Possibly  $K^\pi=3/2^+$  band.

$\gamma(^{157}\text{Tm})$

I<sub>γ</sub> normalization: with the scheme and internal-conversion coefficients given by [1994Xu07](#), the I<sub>γ</sub> normalization is ≈ 0.17. For a more complete scheme, this factor could be much smaller.

Unplaced  $\gamma$ 's are from [1994StZZ](#).
