**2010Dr02** (also **2006Dr04**): E( $^{136}\text{Xe}$ )=830 MeV, ns-pulsed beam with 856 ns pulse separation or macroscopically chopped beam with beam-on/ beam-off conditions ranging from the  $\mu\text{s}$  to the s regimes for out-of-beam data collection Au-backed isotopically-enriched metallic  $^{170}\text{Er}$  target. Measured  $E\gamma$ ,  $I\gamma$ ,  $\gamma\gamma$  coin,  $\gamma\gamma\gamma$  coin,  $\gamma$ - $\gamma$ -t,  $T_{1/2}$  using GAMMASPHERE array at ATLAS-ANL facility. Various timing conditions used to identify isomers and isolate specific structures using  $\gamma$ - $\gamma$ -t correlations. Deduced high-spin levels, J,  $\pi$ ,  $g_{\text{K-gR}}$ . Multi-quasiparticle calculations. No very long-lived isomers were identified.

Note that the authors report a partial level scheme only.

<sup>†</sup> From least-squares fit to  $E\gamma$  values.

<sup>‡</sup> As proposed by **2010Dr02**, based on deduced band properties and comparison with isotone  $^{174}\text{Yb}$ .

<sup>#</sup> From fits to time spectra produced by gating on transitions above and below level (**2010Dr02**).

<sup>@</sup> Band(A):  $K^\pi=0^+$  g.s. band.

<sup>&</sup> Band(B):  $K^\pi=2^+$   $\gamma$  vibration band.

<sup>a</sup> Band(C):  $K^\pi=(4^-)$  band. Dominant configuration= $\pi 7/2[523]+\pi 1/2[411]$ ; supported by experimental band properties and expectations from multi-quasiparticle calculations.

<sup>b</sup> Band(D):  $K^\pi=(6^+)$  band. Possible configuration= $\nu 5/2[512]+\nu 7/2[514]$ . Magnitude of  $g_{\text{K-gR}}$  is similar to that for corresponding band in the  $^{174}\text{Yb}$  isotone, but larger than expected for the suggested configuration.

$^{170}\text{Er}(^{136}\text{Xe}, X\gamma)$  **2010Dr02 (continued)**

$^{172}\text{Er}$  Levels (continued)

<sup>c</sup> Band(E):  $K^\pi=(7^-)$  band. Probable configuration= $v7/2[633]+v7/2[514]$ ; supported by experimental branching ratios. The magnitude of  $g_K-g_R$  and the band structure are similar to those for the corresponding band in the  $^{174}\text{Yb}$  isotope.

This implies $\delta(M2/E1)=0.11$ +4-2, higher than expected for the two-orbital change required by the proposed initial and final state configurations. Alternatively, $\alpha(\text{exp})$ may be high due to a possible issue with systematic uncertainties in the efficiency calibration.

<sup>†</sup> Uncertainty unstated by authors in 2010Dr02 but reported to be 0.2 keV via an email to C.M. Baglin from G. Dracoulis (May 2010). However, 1 keV uncertainty assigned here to  $E_\gamma$  values quoted to the nearest keV.

<sup>‡</sup> From BrIcc v2.3b (16-Dec-2014) 2008Ki07, "Frozen Orbitals" appr. When no  $\delta$  value given, value overlaps listed multipolarities.
