1988Ai02: $E(^{11}\text{B})=60$ MeV Target: ^{210}Pb radioactive target, chemical separation and isotopic enrichment of 50%. Detectors: four Ge detectors and 11 NaI detectors multiplicity filter. Measured: $E\gamma$, $I\gamma$, $\gamma(\theta)$, $\gamma\gamma$ coincidences, excitation function (52-68 MeV, step 2 MeV). Placement of gamma rays to ^{217}Fr were based on coincidences with the francium x-rays and on the analysis of the excitation function data, as well as on comparison of the spectra taken with different folds.

334.0 3		1688.9		1355.0	$23/2^+$	(E2)	Mult.: DCO=1.59 30, but it is also in agreement with a possible $\Delta J=0$, J to J transition.

363.6 3		363.6	$13/2^-$	0.0	$9/2^-$	E2	E_γ : $\gamma\gamma$ coin analysis reveals that 363.6 γ is multiplet and, therefore, the ordering of 340.6 γ and 363.6 γ is not unambiguous, as pointed out in 1988Ai02 . Mult.: DCO=1.32 11; $A_2=0.24$ 6, $A_4=-0.13$ 8.

[†] From [1988Ai02](#). Multipolarities are based on the angular distributions and angular correlations data analysis, and on intensity balance consideration which allowed to differentiate between E1 from M1 alternatives. Since no delayed components were observed, M2 assignments were ruled out for quadrupole transitions. DCO ratios were obtained by gating on known stretched E transitions; expected values are >1 for stretched Q and <1 for stretched D.

[‡] Placement of transition in the level scheme is uncertain.
