

**<sup>208</sup>Pb(<sup>50</sup>Ti,2n $\gamma$ ) 2012Gr12,2009Je01,2011Ro20**

Type	Author	History Citation	Literature Cutoff Date
Full Evaluation	Balraj Singh	NDS 141,327 (2017)	22-Mar-2017

- 2012Gr12:** E=242 MeV <sup>50</sup>Ti beam produced in an ECR ion source using the MIVOC (metallic Ions from volatile compounds) method. Target=446  $\mu\text{g}/\text{cm}^2$  <sup>208</sup>Pb.  $\gamma$  rays were detected using the JUROGAM-II array consisting of 24 clover and 15 tapered Ge detectors with Compton suppression shields. Fission tagging technique. Measured E $\gamma$ , I $\gamma$ ,  $\gamma\gamma$ , energy loss, time-of-flight, recoils, fission products, (fission fragments) $\gamma$  coin. Deduced g.s. rotational band, kinematic and dynamic moments of inertia. No significant deformed shell gap at Z=104.
- 2011Ro20:** <sup>50</sup>Ti beam, E=242.5 MeV produced at the Argonne ATLAS facility. Target=<sup>208</sup>Pb about 0.5 mg/cm<sup>2</sup> thick on a rotating target wheel. Recoiling nuclei identified in the Argonne Fragment Mass Analyzer (FMA) using a position-sensitive parallel grid avalanche counter (PGAC) located in the focal plane based on A/Q, time of arrival and energy-loss signals. Isomeric electron and fission events were detected in the same pixel of a 140  $\mu\text{m}$  thick double-sided Si strip detector that the recoiling nucleus was implanted.  $\gamma$ -rays were detected using four large clover Ge detectors, each consisting of four crystals. Measured electron energies and in coincidence with fission and gamma events, deduced isomer half-life. A total of 783 <sup>256</sup>Rf nuclei were identified from SF decay. No candidates for isomeric transitions were detected within the gamma spectrum in coincidence with the electrons. No evidence was found for a 2-qp isomer in <sup>256</sup>Rf. A predicted 2-qp isomer may decay by SF mode with a half-life close to that of the ground state, thus making its identification difficult. **2011Ro20** discuss in detail many discrepancies with the work of **2009Je01** on the observation of isomers in <sup>256</sup>Rf.
- 2013Ri07:** E(<sup>50</sup>Ti)=238, 243 and 258 MeV. Measured recoil implants and fission correlations at LBNL cyclotron facility using the Berkeley Gas-filled Separator. **2013Ri07** assigned (5<sup>-</sup>) to a 25- $\mu\text{s}$  isomer at 1120 keV, and (8<sup>-</sup>) to a 17- $\mu\text{s}$  isomer at 1400 keV, both first reported in their earlier paper **2009Je01** and described as 2-qp states. Note that in **2011Ro20**, only one weakly populated isomer of 17  $\mu\text{s}$  was found and described as possible 4-qp state.
- 2010Be16:** E(<sup>50</sup>Ti)=238 MeV. Measured E $\gamma$ , ce, E $\alpha$ , (recoils)(ce)( $\alpha$ ), using a DSSD for particles and electrons, and an HPGe clover detector for  $\gamma$  rays at the 88-Inch Cyclotron of the Lawrence Berkeley National Laboratory using the Berkeley Gas-filled Separator. Half-lives of two isomers measured as 13.2  $\mu\text{s}$  <sup>33</sup> and 36.5  $\mu\text{s}$  <sup>86</sup> from recoil- electron-electron-fission(from <sup>256</sup>Rf) correlated events.
- 2009Je01:** E=243 MeV <sup>50</sup>Ti beam provided by 88-Inch Cyclotron at Lawrence Berkeley National Laboratory. Evaporation residues were separated in the Berkeley Gas Separator and identified by coincident signals in the Multi-Wire Proportional Counter and the double-sided Si strip detector.  $\gamma$  rays were detected with a Clover germanium detector. Measured delayed  $\gamma$  rays and conversion electrons, ce- $\gamma$  coincidence, half-lives of isomeric states. Deduced configurations. See also **2013Ri07** where configurations are reassigned based on data for <sup>257</sup>Rf.
- 2008Dr05:** E=4.6-4.8 MeV/nucleon beam provided by 88-Inch cyclotron at LBNL. Detected charged particles using a focal plane detector and a double-sided silicon strip detector. Half-life measured based on the subsequent  $\alpha$ -decay of <sup>256</sup>Rf.

1122 <sup>#</sup> 3	(12 <sup>+</sup> )		of $^{256}\text{Rf}$ g.s.) is much smaller than ≈27% deduced by 2011Ro20 from data in 2009Je01. Due to its low population and several other arguments against its assignment as a 2-qp isomer, 2011Ro20 suggest that their observed 17-μs isomer is more likely a 4-qp state.
≈1400 <sup>‡</sup>	(8 <sup>-</sup> )	17 <sup>‡</sup> μs 2	%IT=?; %SF=? E(level): isomer not found in 2011Ro20, perhaps due to low statistics. T <sub>1/2</sub> : others: 13.2 μs 33 (2010Be16). J <sup>π</sup> : assigned by 2013Ri07 as K <sup>π</sup> =(8 <sup>-</sup> ) with possible 2-qp configuration=(π7/2[514]⊗π9/2[624]) <sub>g-</sub> .
