1971Da16: E=12.12 MeV, multigap spectrograph, $\sigma(\theta)$.

1980Al11: E=17 MeV, polarized beam, magnetic spectrometer, FWHM=40 keV, DWBA predictions of $\sigma(\theta)$ and analyzing power studied.

All data are from 1971Da16.

[†] Weakly excited state adjacent to Si impurity peak.

[‡] From comparison of $\sigma(\theta)$ to states of known J^π .

L=(2+4) for the combined distribution of the 3263 and 3277 level. Yield is for 3263+3277.

@ L=(0+?).
