1977Ha13: E=5.25 and 6.0 MeV proton beams were produced from the T11/25 tandem Van de Graaff accelerator of the NRC Demokritos. Target was a 3.5 mg/cm² self-supporting copper foil (enriched to 99.69% in ^{65}Cu). γ rays were detected with two Ge(Li) detectors. Measured E_γ , I_γ , $\gamma(\theta)$, Doppler-shift attenuation. Deduced levels, J, π , $T_{1/2}$, γ -ray branching ratios, multipolarities and mixing ratios, transition strengths. Comparisons with available data and theoretical calculations.

1968Sm07: E=6.5 MeV proton beam was produced from the MIT-ONR Van de Graaff accelerator. Target was 99.7% enriched ^{65}Cu with a thickness of about 250-280 $\mu\text{g}/\text{cm}^2$. Scattered protons were momentum-analyzed with the MIT multiple-gap magnetic spectrograph; γ rays were detected with a NaI(Tl) detector. Measured E_γ , I_γ , $\text{p}\gamma$ -coin. Deduced levels, J, π , γ -ray branching ratios.

Others:

1976Kr16: E<3.0 MeV. Measured σ .

1978Be40: E=5.0-6.2 MeV. Measured σ . See also (p,p'):IAR.

2021Ta28: E<3 MeV. Measured E_γ , I_γ , σ .
