Introduction

A minimum in the second potential well of deformed nuclei was predicted by Strutinsky [1], and the associated shell gaps are illustrated in the harmonic oscillator potential shell energy surface calculations shown in figure 1 [2,3]. A strong superdeformed minimum in ^{152}Dy was predicted for $\beta_2 \sim 0.75$ [4,5,6]. Subsequently, a discrete set of γ-ray transitions in ^{152}Dy was observed [7] and assigned to the predicted superdeformed band. Extensive research using γ-ray detactor arrays (Gammasphere, Euroball, and GASP) at several laboratories has since focused on searching for superdeformation and predicted hyperdeformation in different mass regions [8–12], together with search for feeding and decay modes of these structures. These bands have been found in several distinct regions near A=40, 80, 130, 150, 163, and 190. Superdeformation ($\beta_2 \approx 0.75$) is also predicted [13] in low mass region for particle numbers 4 and 10 which correspond to ^{8}Be, ^{14}Be and ^{20}Ne nuclides. Quadrupole moment measurements for a large number of cases in each mass region are consistent with assigning the bands to excitations in the second local minimum.

This research extends upon previous work in the actinide region near A=240 where fission (shape) isomers were identified and also associated with the second potential well [14]. A third strong hyperdeformed minimum at $\beta_2 \sim 0.9$ is also predicted as indicated in the figure. Tentative reports for such structures in ^{152}Dy/^{153}Dy [15,16,17] and in ^{147}Gd [18] have not been confirmed in higher statistics data [19–22]

As part of our committment to maintain nuclear structure data as current as possible in the Evaluated Nuclear Structure Data File (ENSDF) [23], we have been updating the information on superdeformed nuclear bands on a continuous basis since 1992. As of July 2002, we have compiled data for about 320 superdeformed bands and 47 fission isomers identified in 146 nuclides for this publication. This is an increase of about 160 superdeformed bands and 53 new nuclides since the second edition in 1996 [24]. The ground state band in ^{20}Ne is also included as possibly a superdeformed structure, although deformation parameter deduced from transition quadropole moment follows an expected $A^{-1/3}$ trend for normal deformed structures. Several bands included here in the A=60 and A=130 regions are highly deformed bands which may or may not correspond to band structures in the second potential well. Partial data for superdeformed bands and fission isomers are shown in the band drawings.

For each nuclide there is a complete level table listing both normal (taken mostly from the ENSDF file, but updated when considered necessary) and superdeformed band assignments; level energy, spin, parity, half-life, magnetic moments, decay branchings; and the energies, final levels, relative intensities, multipolarities, and mixing ratios for transitions deexciting each level. In a few cases normal deformed data from some current references are not included in this table; these references are listed at the end of a table. Proton and neutron separation energies are also provided from the evaluation of Audi and Wapstra [25]. For superdeformed and hyperdeformed bands we provide the following quantities.

Level energies: For SD bands, since the absolute level energies, in most cases, are not yet known, only relative values are given. In the drawings the SD bands are shown with a common baseline for convenient display of multiple bands in a nucleus.

Level half-lives: Measured values are quoted in the tables only.

Level spins: The spin value is generally given only for the first member of the SD band. This value is typically suggested by the authors and has some uncertainty ($\sim$1-2$\hbar$) associated with it. Since linking to normal states is mostly unobserved, except for assignments in ^{133,135,137}Nd, ^{194}Hg, and ^{194}Pb, there is no direct confirmation of these spins. The cascading transitions are all assumed as E2 which is consistent with angular correlation data and short level lifetimes in several cases. The parities are not generally shown because of insufficient evidence at this time.

γ-ray energies: The energies are adopted from the most complete set of data for each band. We have not averaged values because uncertainties are not usually available. Typical energy uncertainties range from 0.1-0.3 keV for intense transitions to 1 keV for weaker γ-rays.

γ-ray intensities: The values given are total relative intensities normalized to $\sim$1.0 for the most intense transition in a superdeformed band or, for multiple bands, to the most intense transition in the superdeformed band. These values are typically read off of the intensity figures in the papers. Correction for internal conversion is assumed to have been applied by the authors. When more than one measurement exists, the most complete set of intensities has been chosen. Absolute intensities can be obtained by multiplying the relative intensities by the %-feeding in Table I.

Moments: Transition Quadrupole moments for SD states are deduced from Doppler broadening of γ-rays. The SD quadrupole moment is typically an average value for the band corresponding to the intrinsic (transition) moment. In the tables the transition quadrupole moments for superdeformed bands are listed as Q_0 values. For fission isomers the quadrupole moments are also intrinsic. The values appear in table 3 and figures 2 and 3, together with β_2(deformation parameter for a quadrupoloid) and X(major to minor axis ratio of an ellipsoid) deduced from measured transition quadrupole moments using the following formulae[26,27]:

$$Q_t = 0.757\ ZR^2\beta_2(1 + 0.36\beta_2)\ 10^{-2}\ \text{eb}$$

$$Q_t = \tfrac{2}{5}\ ZR^2\ \tfrac{X^2-1}{X^{2/3}}\ 10^{-2}\ \text{eb}$$

Where R = 1.2 $A^{1/3}$ fm, A is the atomic mass number and Z is the atomic number.

The dynamic moments of inertia, calculated [28,29] from γ-ray data and with the following definitions have been plotted as a function of rotational frequency at the beginning of the data section:

Rotational frequency:

$$\hbar\omega(J) = \frac{E_\gamma((J+2)\rightarrow J)+E_\gamma(J\rightarrow(J-2))}{4} \text{ MeV}$$

Dynamic moment of inertia:

$$\Im^{(2)}(J) = \frac{4}{E_\gamma((J+2)\rightarrow J)-E_\gamma(J\rightarrow(J-2))}\hbar^2 \text{ MeV}^{-1}$$

Kinetic moment of inertia:

$$\Im^{(1)}(J) = \frac{4}{E_\gamma((J+2)\rightarrow J)+E_\gamma(J\rightarrow(J-2))}\hbar^2 \text{ MeV}^{-1}$$

We have not attempted to label bands according to particle or intruder configurations or according to their isospectral behavior. The reader is referred to the original papers for information about reactions populating these bands and fission isomers. All data published or available untill July 15, 2002 have been included. References with keyword abstracts have been provided from the Nuclear Science Reference (NSR) file [30]. They are divided into three sections for fission isomers, superdeformed band theory, and superdeformed band experimental. The theoretical references before 1986 were not completely scanned for superdeformation.

a Systematics of fission isomers suggest x=1600-2600; y<1000.

b %SF(^{236}U isomer)=13_6, %SF(^{238}U isomer)∼5. For all other isomers, only SF decay has been observed.

c Rotational bands built on these states are shown in the figures.

d Deexcitation to normal states is shown in the figures.

e Some evidence for isomeric decay has been reported.

Plots of Dynamic Moments of Inertia

The dynamic momoents of inertia ($\Im^{(2)}$) are plotted as a function of rotational frequency ($\hbar\omega$). Experimental uncertainties, calculated assuming the γ-ray energy uncertainties can be added in quadrature are shown when available.
